

## Finite Element Method

Prof C. S. Upadhyay

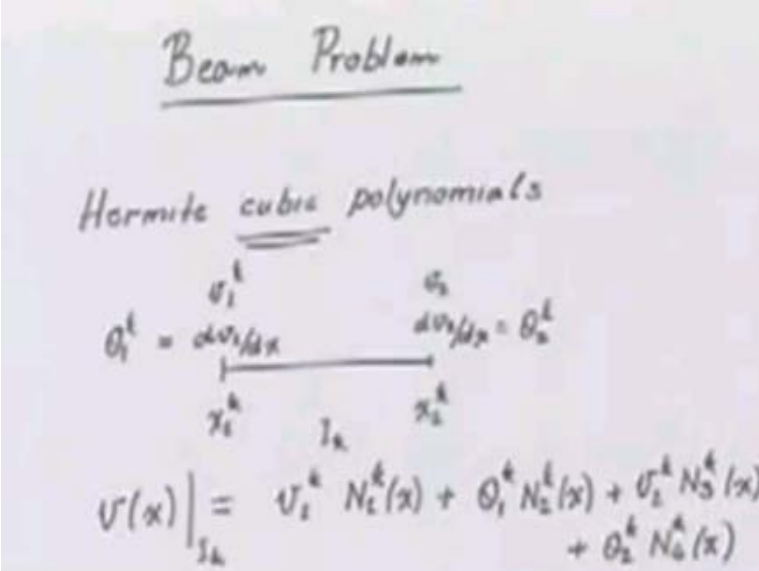

Department of Mechanical Engineering

Indian Institute of Technology, Kanpur

### Module – 6 Lecture – 3

In the previous lecture, we had started talking about the beam problem. What was the difference between the beam problem and the bar problem that we had done earlier? The difference is that the beam problem is a fourth order differential equation. For this, we had defined the weak form; we had also talked about the boundary conditions that are possible. We had started talking about the shape functions that need to be constructed at the element level; the minimum order shape functions in order to satisfy the C one continuity that is imposed by the smoothness requirement that comes out of a weak formulation.

(Refer Slide Time: 00:26)

Beam Problem

Hermite cubic polynomials

$v_1^k$   $v_2^k$   
 $\theta_1^k = dv/dx$   $dv/dx = \theta_2^k$   
 $x_1^k$   $l_k$   $x_2^k$

$v(x)|_{l_k} = v_1^k N_1^k(x) + \theta_1^k N_2^k(x) + v_2^k N_3^k(x) + \theta_2^k N_4^k(x)$

We have said that we are going to construct the so-called Hermite cubic polynomials, which we have said at the element level will lead to an interpolation of the value of... So this is my  $x_1$  of  $k$  element; this is my  $x_2$  of  $k$  for the element  $I_k$ , so it will lead to an interpolation to the value of the displacement at the element level and  $dv_1/dx$  at the element level; similarly, at the two nodes  $v_2$  and derivative here.

So value on the derivative or the slope and the value at the slope at the two ends of the element. So, we need to interpolate between the four values and the minimum order polynomial that will interpolate four values will be a cubic. That is why the starting side of polynomials - the minimum set - is a cubic polynomial. As compared to what we had in the case of the bar problem where the minimum order polynomial was the linear; this was linear; remember that here we start with the piecewise cubic.

We had said that essentially we will write  $v$  of  $x$  is equal to  $v_1$  of  $k$   $v_1$  over the element  $I_k$   $v_1$  of  $k$  into  $N_1 k$  plus - this  $dv_1$  I am going to call it as  $\theta_{a1}$  of  $k$  -  $\theta_{a1} k N_2 k x$  plus  $v_2$  - the displacement at the other end - transverse displacement,  $v_2$  of  $k$   $N_3 k x$  plus - this I am going to call as  $\theta_{a2} k N_4 k x$  - the function of  $x$ . Now it is a question of constructing these polynomials.

(Refer Slide Time: 03:45)

$$\begin{aligned}
 U(x) &= \check{\alpha} + \check{\beta}(x-x_1^k) + \check{\gamma}(x-x_1^k)^2 + \check{\delta}(x-x_1^k)^3 \\
 N_1^k(x) &= 1 - 3\left(\frac{x-x_1^k}{h_k}\right)^2 + 2\left(\frac{x-x_1^k}{h_k}\right)^3 \\
 \rightarrow N_2^k(x) &= +\left(\frac{x-x_1^k}{h_k}\right)\left(1 - \left(\frac{x-x_1^k}{h_k}\right)^2\right) \\
 N_3^k(x) &= 3\left(\frac{x-x_1^k}{h_k}\right)^2 - 2\left(\frac{x-x_1^k}{h_k}\right)^3 \\
 \rightarrow N_4^k(x) &= (x-x_1^k)\left[-\left(\frac{x-x_1^k}{h_k}\right) + \left(\frac{x-x_1^k}{h_k}\right)^2\right]
 \end{aligned}$$

If I go ahead and take  $v(x)$ , as I told you earlier, is equal to some alpha plus beta into  $x$  minus  $x_1$  of  $k$  plus gamma into  $x$  minus  $x_1$  of  $k$  whole square plus delta into  $x$  minus  $x_1$  of  $k$  whole cube. If I took this expansion which is a cubic, here I go and satisfy those conditions, I should be able to obtain the constants alpha, beta, gamma and delta and from these constant I should be able to rearrange everything in terms of  $v_1$  of  $k$  theta<sub>1</sub>  $k$   $v_2$   $k$  and theta<sub>2</sub>  $k$ .

I will get out of that  $N_1$   $k$  of  $x$  is equal to 1 minus 3  $x$  minus  $x_1$   $k$  by  $h_k$  whole square plus 2 into  $x$  minus  $x_1$   $k$  by  $h_k$  whole cubed. Similarly,  $N_2$   $k$  as a function of  $x$  comes out to be: minus  $x$  minus  $x_1$   $k$  over  $h_k$  into 1 minus  $x$  minus  $x_1$   $k$  over  $h_k$  whole squared, this whole square into  $h_k$ . I can effectively cancel this  $h_k$  out; take this one out.  $N_3$   $k$  of  $x$  becomes 3 into  $x$  minus  $x_1$   $k$  by  $h_k$  whole squared by minus 2  $x$  minus  $x_1$   $k$  by  $h_k$  the whole cube. Similarly, my  $N_4$   $k$  as a function of  $x$  comes out to be...  $N_2$   $k$  will have this plus sign here (Refer Slide Time: 06:36 min). Again here it will be  $x$  minus  $x_1$  of  $k$  into minus of  $x$  minus  $x_1$  of  $k$  by  $h_k$  plus  $x$  minus  $x_1$   $k$  by  $h_k$  the whole squared.

$N_1^k$  is  $1 - 3x_1^k/h_k + 2(x_1^k/h_k)^2$  and  $N_2^k$  is  $x_1^k/h_k - 2(x_1^k/h_k)^2 + (x_1^k/h_k)^3$ .  $N_3^k$  is  $3x_1^k/h_k - 2(x_1^k/h_k)^2$  and  $N_4^k$  is  $x_1^k/h_k - (x_1^k/h_k)^2$ . These are the four functions that we have at the element level. Look at one thing that these functions  $N_2$  of  $k$  and  $N_4$  of  $k$  correspond to the slope that is  $dv/dx$  at the two points.  $N_2$  of  $k$  and  $N_4$  of  $k$  - in these there is a difference in the dimension by a factor of  $h_k$ . That is this into  $h_k$  will give you the same dimensional consistency as the  $N_1$  or  $N_3$ . Let us now go and look at how these functions look.

(Refer Slide Time: 08:35)

If I am talking of these functions at the element level the first function  $N_1^k$  should be 1 at this point, at the point  $x_1^k$ , it should have a 0 derivative at this point and it should have a value 0 and the derivative zero here. Why? Because when I put it back in the expression for the value  $v$  at that point becomes is equal to  $v_1$  of  $k$ ; the derivative becomes  $\theta_1$  of  $k$  and so on. So because it is a linearly independent function, it so happen at when you take a derivative you should only be left with the part coming out of in the  $\theta_1$  of  $k$ . This function will be 1 here, the value is 1, slope is 0 and it comes down to value 0 and

slope 0; this is my  $N_1$  of  $k$ . Similarly, let us take the similar one first;  $N_3$  of  $k$  will have a value 1 here, slope 0. So  $N_3$  of  $k$  will be like a mirror image of  $N_1$  of  $k$  this becomes  $N_3$  of  $k$ .

Let's make the  $N_2$  of  $k$ .  $N_2$  of  $k$  what will it have? If I look at  $N_2$  of  $k$ , it should have a slope 1 at this point, value 0 and slope and values 0 at this point (Refer Slide Time: 10:17 min). It should have a slope of 1, value 0 and we come down this. This is my  $N_2$  of  $k$ . If I look at the slope, this angle is 45 degrees; if you want to say that. Similarly, let me make  $N_4$  of  $k$ .  $N_4$  of  $k$  corresponds to  $\theta_2 k$ . It will have a value 0 here, slope of 1 at the point  $x_2$  and value 0 and slope 0 at the point  $x_1$ . So that function will look like this. This is my  $N_4$  of  $k$ . So these are our four shape functions at the element level.

Simple question: what are then the global basis functions? Because remember we are still, as far as the approximation is concerned, we are creating this global basis functions which are  $C^1$  functions and the pieces of this global basis functions are these shape functions in the elements.

Let me draw two of these representative functions. Let us take for example the function which interpolates the value of the  $v$  at this point. Let this be a generic point  $k$ . If I look at this function, in this element, this will be element  $k$ , this will be element  $k$  minus 1. If I look at this, this is going to be my first  $\phi$  - the global basis function and then this corresponds to the value. The second one, let us look at this same point which corresponds to the slope will have a derivative one here. It is going to do something like this and this is my second function. (Refer Slide Time: 12:43 min)

So corresponding to a generic node  $k$ , the first global basis function corresponding to that node is I will call it  $\bar{\phi}$ , is this kind of a function which vanishes at the ends of the elements  $k$  minus 1 and  $k$ , and after that its smoothly goes to 0; stays as 0 everywhere else. The second function  $\bar{\bar{\phi}}$  corresponds to this slope being 1 here, which means it interpolates the slope. You see what it does it has the slope 1 here, value 0 and it comes down finally at the ends of the elements  $k$  minus 1 and  $k$  it becomes 0. This is how

we are going to construct the generic basis functions corresponding to a node  $k$ . Our approximation will be in terms of....So how many basis functions we have now each node? We have 2, because each node in the case of the C one approximation has 2 unknowns assigned to it; these unknowns are the value of the function and value of the derivative of a function. If I have  $N$  nodes, then there will be  $2N$  such functions. My generic approximation, in this case, I can write that  $v$  finite element for an  $N$  noded mesh is  $\sum_{I=1}^{2N} \alpha_I \phi_I$ . Corresponding to the node  $k$  which  $\phi_I$  do we have? So corresponding to the node  $k$  it will be actually equal to  $\phi_I$ , if you check it out it will be  $2k - 1$  and this will be equal to  $\phi_{2k}$  or we will have the basis functions corresponding to the node  $k$  or the  $\phi_{2k-1}$ , in the  $\phi_{2k}$  which goes into the representation of the finite element solution over the whole domain.

(Refer Slide Time: 15:34)

$$\begin{aligned}
 v_{FE}|_k &= \underbrace{v_1^k N_1^k}_{\alpha_{2k-1} \phi_{2k-1}} + \underbrace{\theta_1^k N_2^k}_{\alpha_{2k} \phi_{2k}} + \underbrace{v_2^k N_3^k}_{\alpha_{2k+1} \phi_{2k+1}} + \underbrace{\theta_2^k N_4^k}_{\alpha_{2k+2} \phi_{2k+2}} \\
 &= \sum_{i=1}^4 \alpha_i^k N_i^k
 \end{aligned}$$

Local	Global	
6	1	
1	$2k-1$	$I = 2(k-1) + i$ $i \text{dofs}(k,i) = 2(k-1) + i$
2	$2k$	
3	$2k+1$	
4	$2k+2$	

Now, by the same taken by what we have done here, we have done this, what is then my representation of the finite element solution in the element? Just like we did earlier, we will say that  $v_{FE}$  in the element  $k$  is equal to  $v_1$  of  $k N_1$  of  $k$  plus  $\theta_1$  of  $k N_2$  of  $k$  plus  $v_2$  of  $k N_3$  of  $k$  plus  $\theta_2$  of  $k N_4$  of  $k$ .

It is quite easy to see that what is this corresponding to? This corresponds to the global  $\alpha_{2k-1}$ . This is the piece of the global  $\phi_{2k-1}$ , because the first node of the element  $k$  is the node  $k$ . This corresponds to global  $\alpha_{2k}$  and this corresponds to the global  $\phi_{2k}$ ; this is  $\alpha_{2k+1} \phi_{2k+1}$ ; similarly, this corresponds to  $\alpha_{2k+2}$ ; in this  $\phi_{2k+2}$ .

We could also write that this is equal to at the element level by renaming  $v_1$  of  $k$  and so on.  $I$  is equal to  $1$  to  $4$   $\alpha_I$  of  $k$   $N_I$  of  $k$ , where we understand what are  $\alpha_I$  in the  $k$  mean. If I do this convention of renaming the  $v_1$  of  $k$  as  $\alpha_1$  of  $k$ ;  $\beta_1$  of  $k$   $\alpha_2$  of  $k$ ;  $v_2$  of  $k$  as  $\alpha_3$  of  $k$  and  $\theta_2$  of  $k$  as  $\alpha_4$  of  $k$ . What kind of local to global correspondence do we have? If I write here  $i = 1, 2, 3, 4$ ; this is local; this corresponds to global. Let me write it as big  $I$ ; big  $I$  is equal to  $2i - 1, 2i, 2i + 1, 2i + 2$ ; this is the global. Now it is quite easy to write it an algorithmic way that the global  $I$  is equal to  $2$ ; the global actually should be  $2k - 1, 2k, 2k + 1, 2k$ . This one will be  $2k - 1$  plus  $i$ .

If I write it like this, you check that for  $i$  is equal to  $1$  is become  $2k - 1$ ; for  $i$  is equal to  $2$  it becomes  $2k$ ; for  $i$  is equal to  $3$  it becomes  $2k + 1$ . This I can now load in my  $i$ eldofs. So  $i$ eldofs for the element  $k$ ,  $i$  for the element  $k$  the local  $i$ th degree of freedom is equal to  $2k - 1$  plus  $i$ . This gives me the local to global enumeration. Once we have obtained these things, then I have a complete correlation between the element level approximation and the global approximation.

(Refer Slide Time: 20:12)

The image shows a handwritten derivation of the global stiffness matrix and load vector for a beam element. At the top, it lists the global stiffness matrix  $[K^{(k)}]$  and the global load vector  $\{F^{(k)}\}$ . Below this, the global stiffness matrix is expressed as an integral from  $x=0$  to  $L$  of  $EI(x) \frac{d^2 v}{dx^2} \frac{d^2 w}{dx^2} dx$ . This is equated to the sum of two terms: the integral of  $f w dx$  from  $x=0$  to  $L$ , and the boundary terms  $(V w)|_0^L + (M w')|_0^L$ . The element stiffness matrix is shown as a sum over elements  $k$  of the integral from  $x_1^k$  to  $x_2^k$  of  $EI v'' w'' dx$ . Similarly, the element load vector is shown as a sum over elements  $k$  of the integral from  $x_1^k$  to  $x_2^k$  of  $f w dx$ .

If we now see what does the elements stiffness matrix and the element load vector turn out to be? If you see this, the global stiffness matrix will come from this expression. This will give me the global stiffness matrix and this remember that on the right hand side I have  $x$  is equal to 0 to  $L$   $f w dx$  plus shear force into  $w$  evaluated at 0 and  $L$  plus bending moment into  $w$  prime evaluated at 0 and  $L$ . This quantity plus this quantity is going to give me the load vector. Remember that as we have done earlier for the second order problem, these boundary conditions we are going to impose later. This essentially will go into our load vector - this part (Refer Slide Time: 21:33 min). If I look at first stiffness part, where is it going to come from? The stiffness part, this obviously, will come from the partitioning over the element  $k$ , sum over  $x_1$  of  $k$  to  $x_2$  of  $k$  of  $EI$ . I am now writing the second derivative as the double primes;  $w$  double prime  $dx$ . This is the sum; this integral can be written in terms of this sum; similarly, for the load, I can write sum over the element  $k$  integral  $x_1^k$  to  $x_2^k$  of  $f w dx$ .

(Refer Slide Time: 22:29)

$$\int_{x_1^k}^{x_2^k} EI(x) v''^2 dx = \int_{x_1^k}^{x_2^k} q w dx$$

$$v_{ik} = \sum_{i=1}^4 \alpha_{2k-1+i}^k \phi_{2k-1+i}^k$$

$$\sum_{i=1}^4 \alpha_i^k N_i^k(x)$$

$$[K^{(k)}]_{4 \times 4}, \{F^{(k)}\}_{4 \times 1}$$

So, at the element level which are the integrals that are active? It is  $x_1$  of  $k$  to  $x_2$  of  $k$   $EI$  of  $x$   $v''$  double prime  $w$  double prime  $dx$  and integral  $x_1$  of  $k$  to  $x_2$  of  $k$   $q w dx$ ;  $q$  is my transverse load that I have applied; so I am using  $f$  or  $q$  accordingly here; I am mixing the two, but it should be  $q$ , because according to the convention for beams process load is generally given by a  $q$ . If I look at this, the finite element approximation is replaced here instead of  $v$ ; I know the finite element approximation will be equal to the sum of  $i$  going from 1 to 4  $\alpha_{2k-1+i}^k \phi_{2k-1+i}^k$ . It is a sum of this four and remember that this is equivalent to writing the sum over  $i$  going from 1 to 4  $\alpha_i^k$  of the element  $k$  into  $N_i^k$  of the element  $k$  double prime. Similarly, for the  $q$ , I will get it as sum... here there is no sum involved. In the  $q$ , I will get the integral as integral  $x_1$  of  $k$ ,  $x_2$  of  $k$   $q$ ; it is  $N_i^k$  of  $k$ , because here the  $w$  also what happens?  $w$  is also made of this  $N_i^k$ , because these are the only parts of  $w$  which is non-zero in this element.

For  $v$ , I have this representation; for  $w$ , now I will write, I will put  $w$  is equal to  $N_1^k$  of  $k$  and  $2k$  and  $3k$  and  $4k$  and I will get the 4 equations to which this element is going to contribute. Which columns will it go to? So if I put  $w$  is equal to  $N_1^k$ ,  $N_2^k$ ,  $N_3^k$ ,  $N_4^k$  it means which rows it is going to? It is going to the row  $2k-1$ , row  $2k$ ,  $2k+1$  and

2k plus 2; columns will come from this alpha<sub>i</sub> part, so columns will be the column 2k minus 1, column 2k, column 2k plus 1 and column 2k plus 2. In terms of this element representation, I am going to have the elements difference matrix K to the power k which is of size 4 by 4 and the element load vector for by 1.

(Refer Slide Time: 25:59)

$$K_{ij}^{(k)} = \int_{x_1^k}^{x_2^k} EI(x) N_i^{(k)'} N_j^{(k)'} dx$$

$$F_i^{(k)} = \int_{x_1^k}^{x_2^k} q N_i^{(k)} dx$$

$$x = x_1^k \left( \frac{1-\xi}{2} \right) + x_2^k \left( \frac{1+\xi}{2} \right)$$

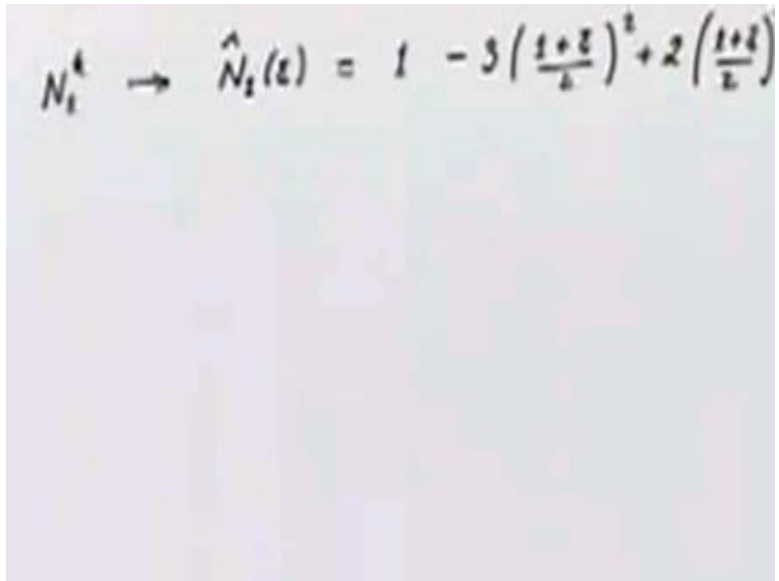

$$\left[ \frac{x - x_1^k}{h_k} = \frac{(1+\xi)}{2} \right] \rightarrow \hat{N}_1(\xi), \hat{N}_2(\xi), \hat{N}_3(\xi), \hat{N}_4(\xi)$$

Let us now give the entries of the element stiffness matrix; it is going to be... we have done enough of this, so we can now go back to what we have done to the previous slide and see that it is going to be EI x N<sub>i</sub><sup>(k)</sup> double prime N<sub>j</sub><sup>(k)</sup> double prime dx and F<sub>i</sub><sup>(k)</sup> is equal to integral x<sub>1</sub> of k to x<sub>2</sub> of k q N<sub>i</sub> of k dx.

The question is that we have done everything at the master element level. How do I convert everything into the master element level? Again we are going to put in the transformation x is equal to x<sub>1</sub><sup>(k)</sup> into 1 minus psi by 2 plus x<sub>2</sub><sup>(k)</sup> into 1 plus psi by two. If I put this transformation then in the definition of N<sub>1</sub><sup>(k)</sup>, N<sub>2</sub><sup>(k)</sup>, N<sub>3</sub><sup>(k)</sup> and N<sub>4</sub><sup>(k)</sup> all I have to do is substitute x minus x<sub>1</sub> of k is divided by h of k is equal to one plus psi divided by 2; we check from here that x minus x<sub>1</sub> of k will be equal to what? x<sub>2</sub> minus x<sub>1</sub> of k into psi by 2, and x<sub>2</sub> minus x<sub>1</sub> is h<sub>k</sub>. x minus x<sub>1</sub> of k divided by h<sub>k</sub> is equal to 1 plus psi by 2.

I substitute this thing in the expressions of  $N_1^k$ ,  $N_2^k$ ,  $N_3^k$  and  $N_4^k$  to get my so-called  $N_1$  hat as a function of  $\psi$ ;  $N_2$  hat as a function of  $\psi$ ;  $N_3$  hat as a function of  $\psi$  and  $N_4$  hat as a function of  $\psi$ .

(Refer Slide Time: 28:45)

$$N_1^k \rightarrow \hat{N}_1(\xi) = 1 - 3\left(\frac{1+\xi}{2}\right)^2 + 2\left(\frac{1+\xi}{2}\right)^3$$

Let me write as an example what will  $N_1$  of  $k$  become?  $N_1$  of will mapped to  $N_1$  hat of  $\psi$  this is equal to 1 minus 1 plus  $\psi$  by 2 whole square plus 2 1 plus  $\psi$  by 2 whole cube. With this simple substitution, I am now able to get the definition of these shape functions at the master element level.

(Refer Slide Time: 29:24)

$$\begin{aligned}
 \underline{K_{ij}^{(k)}} &= \int_{x_1^k}^{x_2^k} EI(x) N_i^{(k)'} N_j^{(k)'} dx \\
 \underline{F_i^{(k)}} &= \int_{x_1^k}^{x_2^k} q N_i^{(k)} dx \\
 x &= x_1^k \left( \frac{1-\xi}{2} \right) + x_2^k \left( \frac{1+\xi}{2} \right) \\
 \left[ \frac{x - x_1^k}{h_k} = \frac{(1+\xi)}{2} \right] &\rightarrow \hat{N}_1(\xi), \hat{N}_2(\xi), \\
 &\quad \hat{N}_3(\xi), \hat{N}_4(\xi)
 \end{aligned}$$

If I have the definition of the shape functions at the master element level, then I can convert these integrals to integrals about the master element level.

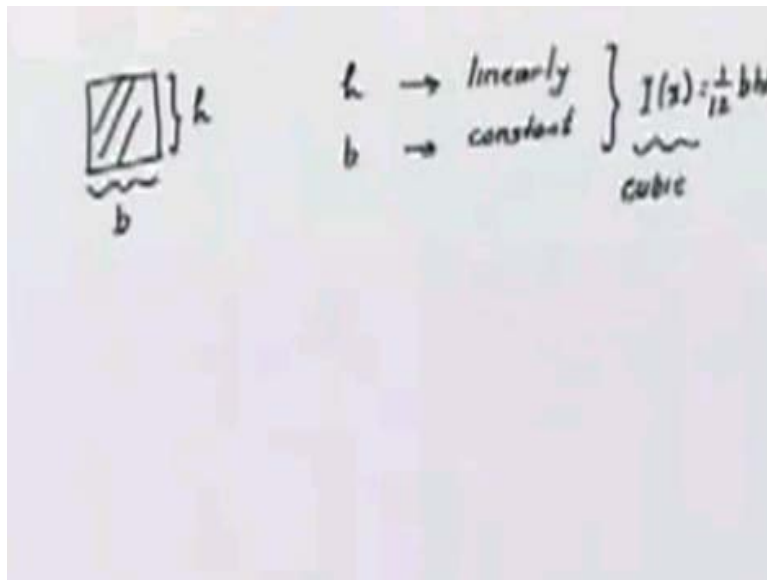

(Refer Slide Time: 29:30)

$$\begin{aligned}
 N_1^k &\rightarrow \hat{N}_1(\xi) = 1 - 3\left(\frac{1+\xi}{2}\right)^2 + 2\left(\frac{1+\xi}{2}\right) \\
 \underline{K_{ij}^{(k)}} &= \int_{\xi=-1}^{+1} \widehat{EI(x(\xi))} \hat{N}_i'' \hat{N}_j'' \left(\frac{2}{h_k}\right)^4 \left(\frac{h_k}{2}\right) d\xi \\
 \frac{d^2 N_i^k}{dx^2} &= \frac{d^2 \hat{N}_i}{d\xi^2} \left(\frac{d\xi}{dx}\right)^2 \rightarrow \left(\frac{2}{h_k}\right)^2 \\
 \underline{F_i^{(k)}} &= \int_{\xi=-1}^{+1} \widehat{q(x(\xi))} \hat{N}_i \left(\frac{h_k}{2}\right) d\xi
 \end{aligned}$$

How will I convert? So what I will get is  $k_{ij}$  over element  $k$  now by doing the conversion minus 1 to plus 1  $EI$  hat now it has become a function of  $\psi$   $N_i$  hat double prime  $N_j$  hat double prime.  $N_i$  hat because  $d^2 N_{ik} dx^2$  is equal to  $d^2 2N_i$  hat  $d\psi$  squared into  $d\psi$  by  $dx$  whole square. This  $d\psi$  by  $dx$  whole square is nothing but as we have defined the Jacobean earlier 2 by  $h_k$  the whole squared. I will have here 2 by  $h_k$  whole to the power 4 because for each one of them now the Jacobean. This is what my  $k_{ij}$  is going to look like at the element level.

Similarly,  $F_i$  for the element  $k$  will look like this: minus 1 to plus 1  $q$  becomes now a function of  $\psi$ . So I make it  $q$  hat into  $N_i$  hat into  $h_k$  by  $2d\psi$ . In the element load vector  $N_3$  becomes this. Let us see what is the integration rule we have to use? So we are going to use the [ ] quadrature that we have defined. The question is what is the order of the integral - maximum order?

(Refer Slide Time: 32:08)

Let us assume at least for the problems that we are trying to solve, let's say that we have this beam with a rectangular cross section. For this cross section this is the height  $h$ , this is the width  $b$ . We say that  $h$  varies linearly and  $b$  is constant; that is, the height varies

linearly, that is, I have tapering in the height, while the depth remains the same. In this case  $i$  as a function of  $x$  is equal to one-twelfth  $bhh$  cube. So  $i$  varies as a cubic, because  $h$  is linear, so  $i$  is one-twelfth of  $bh$  cube; it becomes a cubic.

(Refer Slide Time: 33:10)

$$N_i^k \rightarrow \hat{N}_i(\xi) = 1 - 3\left(\frac{1+\xi}{2}\right)^2 + 2\left(\frac{1+\xi}{2}\right)^3$$

$$K_{ij}^{(k)} = \int_{\xi=-1}^1 \widehat{EI(x(\xi))} \hat{N}_i'' \hat{N}_j'' \left(\frac{2}{h_0}\right)^4 \left(\frac{1}{2}\right) d\xi$$

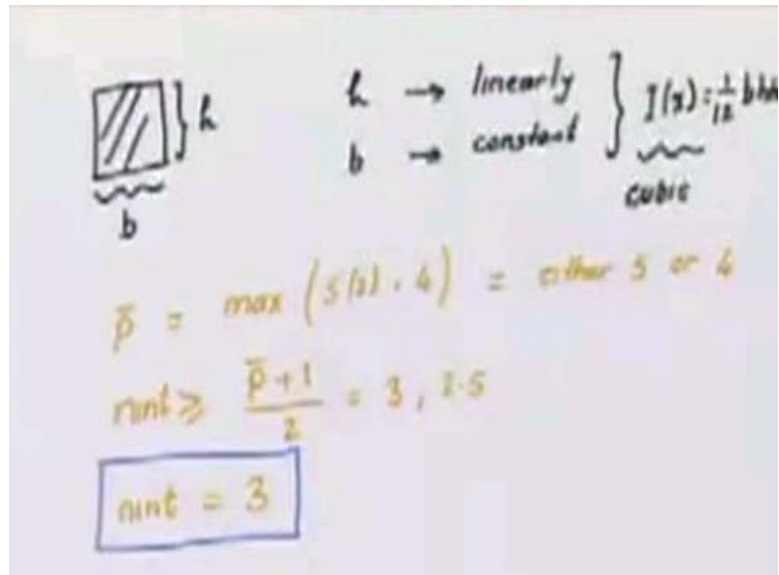

$\frac{d^2 N_i^k}{d\xi^2} = \frac{d^2 \hat{N}_i}{d\xi^2} \left(\frac{d\xi}{dx}\right)^2 \rightarrow \left(\frac{2}{h_0}\right)^2$

$$F_i^{(k)} = \int_{\xi=-1}^1 \widehat{q(x(\xi))} \hat{N}_i \left(\frac{h_0}{2}\right) d\xi$$

If  $i$  is a cubic, if I go back to my integral here, so  $EI$  is a cubic. So if I write it here  $EI$  is a cubic, it is of order three. The second derivative of  $N_i$  since,  $N_i$  was cubic, second derivative linear, second derivative of  $N_j$  is linear. The order of the integrand is 5, if I have taken the beam to be a tapered beam; if it is a beam of constant cross section that is  $h$  and  $b$  are both constant, then this part will become 0. So this integrand is essentially of order 2.

Similarly, if I look at  $F_i$ , let us say that I am interested at most in a loading, which is linear; that is, I will have the constant loading and I have the step loading, triangular profile. The loading is linear, if the loading is linear, the  $q$  is linear  $N_i$  is cubic. The integrand is of order 4. Let me write here within bracket incase my  $EI$  is a constant.

(Refer Slide Time: 34:36)

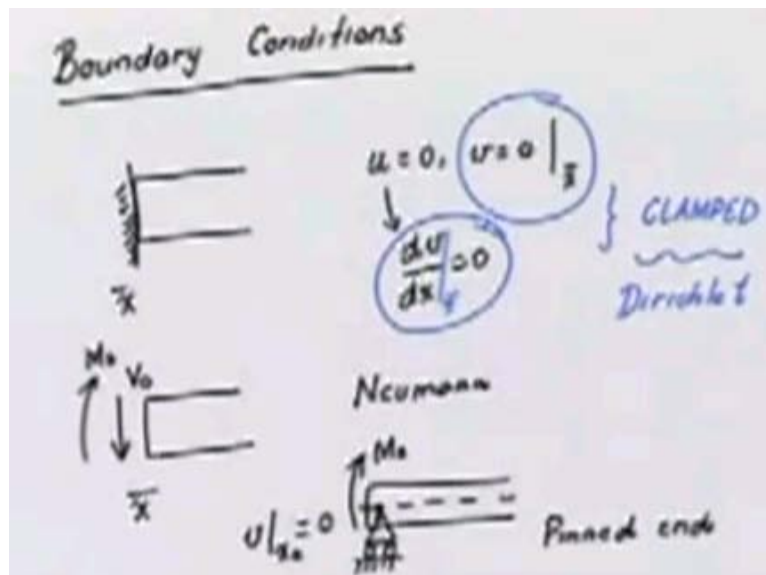

My integrand  $E$  bar, if you remember, will be equal to max of 2 or 4. This is equal to either 5 or 4; with the understanding that this 5 when I have a tapered beam and it is 4 when I have a beam with constant cross section.

In this case, if the integrand is of this order, then we know that the integration rule, the number of points, so I have to have  $n_{int}$  is greater than equal to  $\bar{p}$  plus 1 by 2. In this case, it is equal to if I take 5 then 3 and if I take 4 it will become 2.5. So  $n_{int}$  is equal to 3 will do the job. If we take the 3-point integration rule, we will get exact integrals as far as the stiffness part is concerned and as far as the load part is concerned. Remember that these are procedures which are now very similar to what we have done. If I want to incorporate this in my finite element program which I have already written, I do not have to change much; all I say the  $p$  processor you see that the mesh will be the same; the degree of freedom numbering how will I do? I will go and simply... If it is the bar problem I will do the degree of freedom numbering according to the bar with the order of approximation we can choose; in the case of the beam we are only going to look at the Hermite cubic we could raise the order of approximation, but let us say it is only Hermite

cubic; so we choose for the beam the Hermite cubic and then we can give a degree of freedom numbering as I have just shown, the ieldof can be created, no problem.

After I have done all those things, then I choose the integration points; I have the integration points and there again at these integration points I can load the values of the shape functions, the derivatives of the shape functions and now in this case the second derivative of the shape functions also we are going to store. Go to the element calculation, do the element calculation, do the assembly and continue from there.

(Refer Slide Time: 37:27)

This is how we are going to do the whole procedure. So adding this part to the one-d code should not be difficult. Now, what about the boundary conditions? So, the boundary conditions, let us take some basic types of boundary conditions, I can have at each of the end, the case which corresponds to a clamped end.

Here I am saying  $u$  is equal to 0 and  $v$  is equal to 0 at the point  $\bar{x}$ . Now  $u$  by its representation it means that through the height it is 0, which means that this will give me  $dv/dx$  is equal to 0, because  $u_0$  was 0 for the problem the way we have done it. So  $u$

becomes equal to minus  $y \frac{dv}{dx}$ ; now for all  $y$  this has to be 0; so  $\frac{dv}{dx}$  is 0. This condition where I am specifying  $v$  is equal to 0 and  $\frac{dv}{dx}$  equal to 0 at the point  $x$  bar - this is called clamped end. We have talked about the clamped end and this is nothing but our Dirichle's boundary condition, that is both  $u$  and  $v$  are fixed. We can have a mixture of things also, let us see.

We can also have a second type of boundary condition at this point  $N$  where I am specifying the bending moment and the shear force. That is the bending moment and the shear forces are given. So, this is our Neumann end. Now the bending moment and the shear force could be 0 which corresponds to a free end. This is a Neumann boundary condition.

I could have another situation where I am fixing the middle line of the bar, have to be at this point. What I am saying here is  $v$  at this point is equal to 0. If  $v$  is 0, then I am actually allowed to give a moment if I want - a rotation. I can apply moment  $M_0$  or I leave it free. This is called pinned end.

Remember what we had said is the displacement and the shear force occur together in pairs and the bending moment and the slope occur in pairs. If the displacement is specified certainly I cannot specify the shear force, but here I have done nothing about this slope. So, I can apply a bending moment there. I have to apply a bending moment there; the slope could be anything.

(Refer Slide Time: 40:50)

$$\Pi = \frac{1}{2} \int_{x=0}^L EI(x) \left( \frac{d^2v}{dx^2} \right)^2 dx - \int_{x=0}^L qv dx - (Mv)' \Big|_0^L - (Vv)' \Big|_0^L$$

In general, see in most of the examples that you see, this bending moment is said to be 0. Similarly, I could have another special boundary condition, where I have  $x$  bar moving in a guided slot and this is our rigid support; the rigid support is moving in a guided slot. So what happens because of this I have a  $dv/dx$  at  $x_0$  equal to 0, it is not allowed to bend, but I could certainly at the same time, specify a shear force  $v$ . So we can have various types of boundary conditions; one can take many more, but these are quite sufficient, at least for most of the problems that we are looking at. These boundary conditions can also be incorporated exactly the way we did it for second order for the bar problem, this can be incorporated for the beam problem where ibc type at the two ends. Now, this ibc type can be given various numbers: 1 mean clamped; 2 means bent; 3 means free; 4 means rigid; rigid free; rigid on a roller. So we can give these flags at each end and according to the flag, we specify what is the data which has to be input. Accordingly, because  $dv/dx$ , for example here is fixed, so I have to go and constraint the  $dv/dx$  to be equal to 0 in my final system. So once I have obtained element calculations, done the assembly, then I now appropriately add the boundary conditions; that is add either the boundary forces and moments or constraint the boundary displacements on the slopes to the given values.

Again, the same procedure that we have followed. Once we have this, then now we are in a position to solve the problem. We can solve this problem in terms of how many unknowns, if it has any LEM number of elements, then I have  $n_e$  LEM plus one node twice into  $n_e$  LEM plus one is the  $n_{dofs}$ , the total number of degrees of freedom that we have; that is all. We solve for that many degrees of freedom, get the solution and we are done.

Another thing that you should be able to do now, we have done the principle of virtual function. We could also derive everything that we have done from the total potential energy, where the strain energy is given by, as we you know from a basic mechanics,  $EI$  of  $x$  minus integral  $x$  is equal to 0 to  $L$   $q v dx$  minus  $M v prime$   $v prime$  at 0 to  $L$  minus  $v$  into  $v$  as defined.

So if I define the total potential energy like this, which is what we have the strain energy due to the bending, work done by the distributed force, work done by the  $N$  moment work, done by the end shear forces, then by taking the first variation of this we should get exactly the weak formulation that we have obtained. Now, the question is that this was just a remark - we could derive it anyway we wish - that how do we post process the solution? What is the information that we need?

(Refer Slide Time: 44:53)

The image shows a whiteboard with handwritten mathematical expressions. At the top, there is a simple diagram of a beam element of length \$L\$, fixed at the left end. Below the diagram, the following equations are written:

$$M(x), \sigma_{xx}|_{max}, V(x)$$

$$M|_{I_k} = EI(x) \left. \frac{d^2 v}{dx^2} \right|_{I_k} = \sum_{i=1}^4 (\alpha_i^k N_i^{(e)}) EI(x)$$

$$V|_{I_k} = - \left. \frac{d}{dx} (EI \frac{dv}{dx}) \right|_{I_k}$$

The summation index \$i\$ is noted as \$i = 1 \uparrow\$ and the coefficient \$\alpha\_i^k\$ is noted as \$\alpha\_{2k-i+1}\$.

Out of this, if I have this beam, I will be interested in the bending moment distribution, I will be interested in the actual stress  $\sigma_{xx}$  distribution, I will be interested in  $\sigma_{xx}|_{max}$  at that point, I may be interested in the shear force at that point; these are the quantities that I may be interested in, to get from the finite element solution. How will I get to M of x? So in an element  $I_k$ , I could do it globally or I can do it in an element, this M of x is equal to, M in the element  $I_k$  is equal to EI x into d two v dx squared in the element  $I_k$ , but this if I can write it: i is equal to 1 to 4,  $\alpha_i^k N_i^{(e)}$  whole thing into EI of x.

So I know what  $\alpha_i^k$  corresponds to from the global to local enumeration. So I find the value; this is  $\alpha_{2k-1+i}$ , I find the value of this degree of freedom multiply it with the second derivative of the shape function that we have obtained the value of the material property – the flexural rigidity at the given point x. This way put it in, I can find the value of the bending moment at any point in the element. So by interpolation we can find. Similarly, for the shear force; shear force, in this case, in this element if you see it will be this (Refer Slide Time: 47:06 min). Let us assume, for the time being that EI is constant, then this essentially means this is nothing but the third

derivate of  $v$ , which in the element is a constant, because we have taken a cubic. So VI for uniform flexibility is a constant. So post-processing is not a problem if  $EI$  is not a constant, then I can go and put it again in the formula that we have written. So this way we can find bending moment and shear force at every point.

(Refer Slide Time: 47:44)

$$\underline{M(x)}, \quad \sigma_{xx} = \frac{M(x)y}{I} = \left( \sum_{i=1}^4 E \alpha_i^k N_i^{(k)} \right) y$$

$\alpha_{11-1} \rightarrow v$   
 $\alpha_{21} \rightarrow \theta$

exact if  $EI = \text{Constant}$

$\frac{d^2 w}{dx^2}$  is very good at  $\xi = \pm \frac{1}{3}$

Now given a bending moment at a point  $x$ , finding  $\sigma_{xx}$  is not a problem. It is equal to  $M_x$  at this point  $y$  by  $I$ ; so this will be equal to  $\sigma_{xx} = \frac{M(x)y}{I}$ ; so this will be equal to  $\sigma_{xx} = \frac{M(x)y}{I} = \left( \sum_{i=1}^4 E \alpha_i^k N_i^{(k)} \right) y$ . So where is it maximum – at the top or the bottom? So I go to plus minus  $h$  by  $2$  or whatever is my maximum value of the  $y$ , because, it may not be that the neutral axis is at the mid point; neutral axis could also be at shifted depending on what is the cross sectional parameter. So I find the value of this at the top and the bottom and see which one is the higher, and that is how I will find  $\sigma_{xx \max}$ , if I need to.

Given a mesh, the values of  $\alpha$  for a node  $\alpha_{2i-1}$  and  $\alpha_{2i}$ , for a node  $I$ , these values correspond to  $v$  at this point; corresponds to  $\theta$  at this point; values are exact if  $EI$  is equal to constant. So for constant flexible rigidity the nodal values of the displacements, that is the  $\alpha$ s that we have obtained, they correspond to the transverse

displacement and the slope at this point and they turn out to be exact, provided that EI is constant. If EI is not constant, but if it is smooth then the nodal values are very good, but are not exact. Similarly, I can talk of now, how the bending moment behaves. If I have this cubic approximation, I will find in an element the bending moment, if I look at the error in the second derivative, it will be something like this. So what I will get is  $d^2 w_{FE} / dx^2$  is very good at actually the points corresponding to the two-point integration rule; that is at  $\xi$ , if I go to the master element plus minus 1 by root 2. So these are the points where the second derivative of the  $w$  are going to be very good, similarly, because, the second derivative of the  $w$  here is a linear.

(Refer Slide Time: 51:00)

$$M(x) = EI(x) \frac{d^2 w_{FE}}{dx^2}$$

$$V(x) \rightarrow \text{very good at the centre of the element } (\xi \rightarrow 1\text{pt-rule})$$

$$\frac{d^2 w^e}{dx^2} = a_0 + a_1 x + a_2 x^2$$

$$J^{(k)} = \frac{1}{2} \sum_{i=1}^6 EI(x(\xi_i)) \left( \frac{d^2 w^e}{dx^2}(\xi_i) - \frac{d^2 w_{FE}}{dx^2}(\xi_i) \right)$$

So if I say that, then  $M$  of  $x$  is equal to  $EI \times d^2 w_{FE} / dx^2$  is very good at two points in the element and these two points correspond to in the master element  $\xi$  equal to plus minus 1 by root 3. Similarly, if I talk of  $v$  of  $x$ , this will be very good at the centre of the element. Or we can say it corresponds to the point  $\xi$  corresponding to the one-point integration rule. So, essentially if I really want to pick up the good values of  $M$  of  $x$  and  $d$  of  $x$ , I can pick them up at these points.

Now there is another question imagine that I would now like to get a good value of  $M$  of  $x$  at every point in the element (Refer Slide Time: 52:22 min). So again what would I do? I have essentially, the neighbors  $k$  minus 1 and  $k$  plus 1; for the neighbors, I know that for each of the elements, there are two points where the second point of  $w$  is good. So I will take these points, let us say  $\psi_{i_1}$  of  $k$  minus 1, this is  $\psi_{i_2}$  of  $k$  minus 1 and so on,  $\psi_{i_1}$  of  $k$ ,  $\psi_{i_2}$  of  $k$ ... I will number them in a sequence; there are 6 such points. So I will call the six points  $\bar{\psi}_i$ , in this set of three elements. If I look at this  $d^2 w / dx^2$  is a linear. I will now say that I want to get an approximation which is quadratic. Then, I will define how I will find these co-efficients? I hope that what I am getting is better than what the finite element solution gave me.

So I am going to define a  $J$  which is sum over  $i$  equal to 1 to 6; this is for the corresponding to the element  $k$   $EI$  at the point  $x$  corresponding to the point  $\bar{\psi}_i$  into  $d^2 w^* / dx^2$  at the point  $x$  corresponding to  $\bar{\psi}_i$  minus  $d^2 w_{FE} / dx^2$  at the point corresponding to  $\bar{\psi}_i$  whole squared. So I defined this discrete sum over the six points where the six points are the two-point rule in the elements  $k$ ,  $k$  minus 1 and  $k$  plus 1. So this I will define for the element  $k$ . Now, I want to minimize this. So I want the co-efficients  $a_{0k}$ ,  $a_{1k}$ ,  $a_{2k}$  such that this is minimized. I get the set of equations knowing what is the  $w_{FE}$ ; this is known. I can find  $d^2 w^* / dx^2$  from this fit, I can find these coefficients  $a_{0k}$ ,  $a_{1k}$ ,  $a_{2k}$  just like we had done in the earlier case.

(Refer Slide Time: 56:00)

$$M_k^* = EI(x) (a_0^k + a_1^k x + a_2^k x^2)$$

$$\sigma_{xx}^* / k = E (a_0^k + a_1^k x + a_2^k x^2) y$$

Diagram of a beam element of length  $L$  with a distributed load  $k(x)$  and a reaction force  $k_0$ . The integral equation is:

$$\int_{x_0}^L k(x) w dx = k_0$$

Once I have obtained these co- efficient, then I can say that my M star in the element k is equal to EIx into  $a_0^k$  plus  $a_1^k x$  plus  $a_2^k x$  to the power 2. So if I go back again this exercise, this fitting has to be done for each element, where for the element I take two neighbors and from there I am fitting this quadratic polynomial using the values at these six points. Once I have done this, then for each element I can construct the solution and I can construct the M, as I have constructed the M, I can construct the  $\sigma_{xx}$  star at the element K is equal to E into  $a_0^k$  plus  $a_1^k x$  plus  $a_2^k x$  squared into y. This is how we can construct the recovered value of the stress. This is essentially an extrapolation of what we had done for the second order differential equation. So this is also a patch recovery method, but used for the beam problem. You can see that this will give quite decent values of the received bending moment and the actual stress that we obtain.

So, now we have been able to reach a proper procedure for solving for the actual bar problem and a beam problem. Now, in general, I could also look at some extensions of this, maybe the beam is sitting on an elastic support that is on a distributed spring with this I will only change the stiffness matrix part, that is for the stiffness part I am going to add  $k$  of  $x$   $w_{FE}$  into  $w dx$ . I could have my member supported by one spring, then at this

point I have to ensure that I have a node and at this point I simply go and take care of this by adding  $k_0$  to the diagonal entry corresponding to the displacement at this node.

So these are certain things that now can be easily handled. I could also handle the problem I have a distributed load which is transverse and an actual force and an end load. That is you can look at the combined beam-bar problem; that is both **impend** loads and transverse loads are there; in this case, we will also have the actual displacement; the actual displacement will give me the second order differential equation; the transverse will give me a beam which is a fourth order differential equation. So we can combine the two and solve the problem. In this case what will happen is at every node you will have the  $u$ ,  $0$ ,  $v$  and  $dv/dx$  as the unknowns; so there will be a three unknowns. This is not a big problem. Once we have understood how to do these things, you can handle this. So essentially, in a one-dimensional problem this is what we are going to look at.

Next class we are going to start on the two- dimensional boundary value and we are going to elaborate about how to go about adapting what we have done without major changes to the two-dimensional problem.
