**Module – 8 Lecture – 1**

In this lecture we are going to go further with the definition of higher order shape functions for two-dimensional problems. We were working with triangular elements. How do I construct higher order approximation, that is, an order greater than two for a triangular element?

(Refer Slide Time: 00:45)

Here are the corners of the master element. Given the order, the shape functions should become the one dimensional shape function, when I project them on a given edge of the triangle.

If this is node 1, node 2, node 3 and if I am talking of the first edge connected to nodes 1 and 2; and if I am talking of P equal to 3, a cubic approximation, that approximation or those functions should become the one dimensional cubic shape functions on this edge. The one-dimensional cubic shape functions, in terms of definition - the Lagrangian functions, correspond to these four

points on this edge, that is, these four equally spaced points. This point will correspond to the coordinate one-third, zero, this will correspond to two-third, zero and this is one, zero.

Similarly, on this edge, I should have the four equally spaced points given by these locations. Here the coordinate will be  $\psi$  is equal to two-third,  $\eta$  is equal to one-third, while this one will be  $\psi$  equal to one-third,  $\eta$  is equal to two-third because  $\psi + \eta$  has to be one. On this edge I will have two more points, which are given by  $\eta$  is equal to two-third and  $\eta$  is equal to one-third. I have made 1, 2, 3, 4, 5, 6, 7, 8, 9 points. For  $P$  equal to 3 from the Pascal triangle we had drawn earlier, we needed  $(P+1)$  into  $(P+2)$  by 2 (number of monomials) for completeness. For  $P$  equal to 3, this is equal to 10. So nine points means nine definitions of Lagrangian shape functions. We need one more to give us ten independent basis functions.

Let us say that I connect these points by straight lines. If I have drawn everything correctly, they should pass through like this. I have connected these points by a straight line, these two points by a straight line and then I draw straight lines parallel to the three edges. If I look at these straight lines, they intersect at an interior point. This interior point will have a coordinate. It lies on the line  $\eta$  is equal to one-third and on the line  $\psi$  is equal to one-third. So it will have a coordinate one-third, one-third. This is nothing but the centroid. This point is another node. This becomes the tenth node. Our shape functions are now defined. Now I am going to color the nodes with respect to these ten nodes and I will follow some numbering scheme. Let us say, as far as the definition of shape function is concerned, this is 1, this is 2, this is 3, this is 4, this is 5, this is 6, 7, 8, 9 and 10. I need ten cubic basis functions in order to have a complete set, which can completely represent any cubic polynomial.

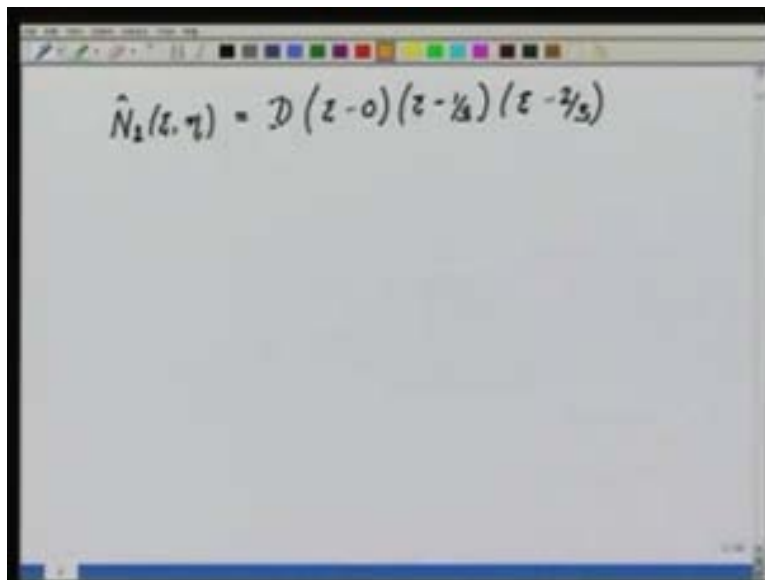

How do I now go about defining the shape functions? Let us say I would like to define  $N_1$  as a function of  $\psi$  and  $\eta$ . This function  $N_1$  is with respect to this node such that  $N_1$  is 1 at the nodes with coordinates zero, zero and zero at all other nodes.

How can  $N_1$  be a cubic polynomial in terms of  $\psi$  and  $\eta$  and vanish at all other nodes barring node 1? I will put  $N_1$  as  $\psi$ . If I take the  $N_1$  to vanish on this line, which is nothing but the line  $\psi + \eta$  is equal to one-third, make it vanish on this line which is the line  $\psi + \eta$  is equal to two-third and on this line which is  $\psi + \eta$  is equal to one. So if I choose  $N_1$  to vanish on these three lines, then automatically  $N_1$  vanishes on all other nodes barring the first node. So I

will say, it will have to vanish on the line  $\psi + \eta = \frac{1}{3}$ . So  $\psi + \eta$  is minus one-third. It has to vanish on the line  $\psi + \eta = \frac{2}{3}$ , so  $\psi + \eta$  minus two-third and it has to vanish on the line  $\psi + \eta = 1$ . So it is  $\psi + \eta - 1$ . This is going to give the  $N_1$  such that  $N_1$  hat at the point zero, zero, which is the first point is equal to 1. This is equal to  $c$  into minus one-third into minus two-third into minus 1.  $C$  implies  $c$  is equal to minus nine by two. So it is quite easy to find the definition of the first shape function.

Similarly, if I want to find  $N_2$ ,  $N_2$  is a function, which is one at this point and vanishes at all other points. It simply means that it has to vanish along this line, vanish along this line, vanish along this line and vanish along this line.  $N_2$  is now written in terms of equation of this line. Equation of this line is  $\psi = \frac{2}{3}$ ; equation of this line is  $\psi = \frac{1}{3}$ ; and equation of this line is  $\psi = 0$ .

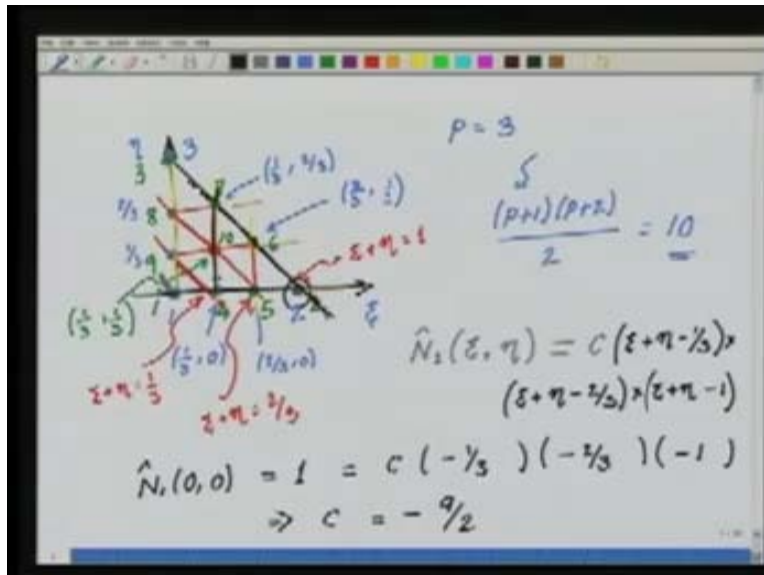

(Refer Slide Time: 08:37)

$$\hat{N}_2(\psi, \eta) = D (\psi - 0) (\psi - \frac{1}{3}) (\psi - \frac{2}{3})$$

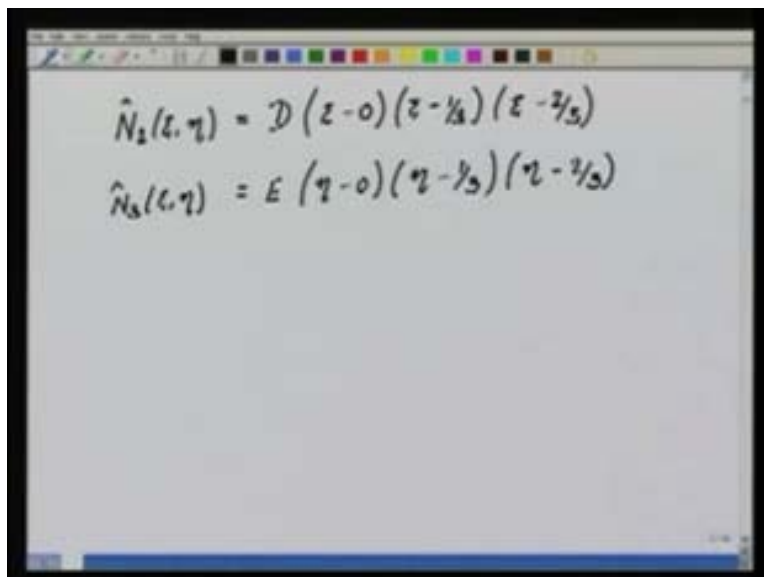

$N_2$  hat, which is a function of  $\psi$  and  $\eta$  is, let us say, some constant  $D$ . It has to vanish on the line  $\psi = 0$ , so  $\psi - 0$ , into (on the line  $\psi = \frac{1}{3}$ )  $\psi - \frac{1}{3}$ , into (on the line  $\psi = \frac{2}{3}$ )  $\psi - \frac{2}{3}$ .

(Refer Slide Time: 09:00)

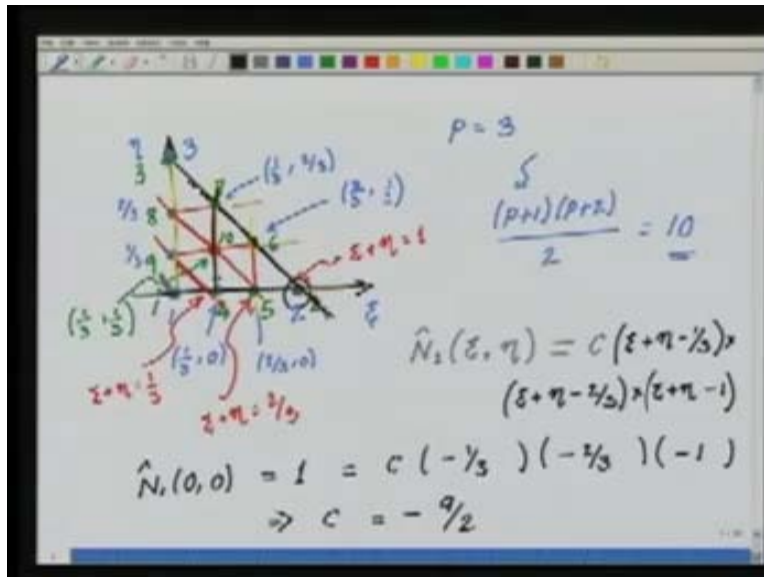

$N_3$  vanishes on this line, vanishes on this line and vanishes on this line. Equations of these lines are:  $\eta$  is equal to zero,  $\eta$  is equal to one-third,  $\eta$  is equal to two-third. We should have a value one at the node three.

(Refer Slide Time: 09:21)

$N_3$  will be some constant  $E$  into  $\eta$  minus 0 into  $\eta$  minus one by three into  $\eta$  minus two by three.

(Refer Slide Time: 09:43)

If I have to find  $N_4$ ,  $N_4$  has to be one at this point and zero at all other points. If  $N_4$  has to be taken to be zero at all other points,  $N_4$  has to be zero on this line. It has to be zero on this line and it has to be zero on this line. Equation of this line is  $\xi + \eta = \frac{1}{3}$ . Equation of this line is  $\xi + \eta = \frac{2}{3}$ . Equation of this line is  $\xi + \eta = 1$ .

By the same token, if I want to construct  $N_8$ ,  $N_8$  will be 1 at the node 8 and it should be zero at all other nodes, which means that it has to be zero. If I take it to be zero on this line, zero on this line, which takes care of all these nodes and zero on this line, then  $N_4$  is taken care of.

Similarly, I can define  $N_{10}$ .  $N_{10}$  has to vanish on the three edges of the triangle. If I have to talk of  $N_{10}$ ,  $N_{10}$  will be zero along this line, which is  $\eta = 0$ , 0 along this line which is  $\xi = 0$ , 0 along this line which is  $\xi + \eta = 1$ .

(Refer Slide Time: 11:19)

$$\hat{N}_2(z, \eta) = D (z-0)(z-\frac{1}{3})(\eta-\frac{2}{3})$$

$$\hat{N}_3(z, \eta) = E (\eta-0)(\eta-\frac{1}{3})(z-\frac{2}{3})$$

$$\vdots$$

$$\hat{N}_{10}(z, \eta) = F (\xi-0)(\eta-0)(\xi+\eta-1)$$

p=4  $\rightarrow$  15 shape fns

$N_{10}$  is the function of psi and eta is equal to F into psi minus 0 into eta minus 0 into psi plus eta minus 1. I can construct this way, all the shape functions that we need in the master element. If I want to now go to  $P = 4$ ,  $P = 4$  will require, by our definition of  $(P+1)(P+2)/2$  monomials, to define a fourth order polynomial. This will require 15 shape functions to be defined.

(Refer Slide Time: 12:08)

$p=3$

$$\frac{(p+1)(p+2)}{2} = 10$$

$$\hat{N}_1(z, \eta) = c (z+\eta-\frac{1}{3}) (\xi+\eta-\frac{2}{3}) (\xi+\eta-1)$$

$$\hat{N}_1(0,0) = 1 = c (-\frac{1}{3}) (-\frac{2}{3}) (-1)$$

$$\Rightarrow c = -\frac{9}{2}$$

Let me give some notations. These corner degrees of freedom are called the vertex degrees of freedom. These degrees of freedom on the edge are called the side degrees of freedom and this interior degree of freedom, which is ten, is called the interior degree of freedom. Ten is non-zero in the given element. It is going to be zero outside this element. Ten is called an internal bubble function. These edge functions are going to be non-zero only in the two elements, which share this edge. So these are called side bubble functions. The vertex functions are non-zero in all the elements, which have this vertex as a common vertex.

(Refer Slide Time: 12:59)

$$\hat{N}_2(\xi, \eta) = D (\xi - 0) (\xi - \frac{1}{2}) (\xi - \frac{2}{3})$$

$$\hat{N}_3(\xi, \eta) = E (\eta - 0) (\eta - \frac{1}{3}) (\eta - \frac{2}{3})$$

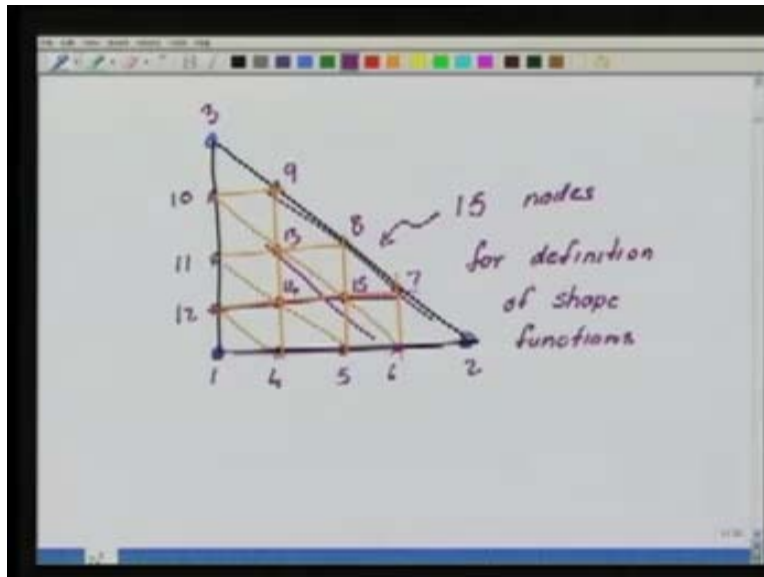

$$\vdots$$

$$\hat{N}_{10}(\xi, \eta) = F (\xi - 0) (\eta - 0) (\xi + \eta - 1)$$

p=4  $\rightarrow$  15 shape fns

Let us now see how to do the P=4 case.

(Refer Slide Time: 13:17)

We will make these vertices. When I project the shape functions on the edges of the triangle, they should become equivalent to the one-dimensional fourth order shape functions (defined in the one-D case) on this edge. They are given by specifying five equally spaced points on the line  $P+1$ . So I have these three points here. Then I will have these three points here and similarly, three points here on these edges.

If we count all these points, I have 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12. As far as the vertex and edge functions are concerned, there are only twelve side functions. So I need to have three more functions, which are now internal bubbles. We connect these points with straight lines on opposite edges. I have constructed these additional internal points in this grid. I define the shape functions for all these points. There are exactly three internal points and fifteen points with respect to which I define the shape functions. Here I have fifteen nodes for the definition of shape functions. I follow the same procedure as before to define the shape functions.

For example, if I have to find the shape function corresponding to this one, let us give the numbering 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 and 15. Let us say I am interested in the eleventh one. The eleventh one should be such that it is one at this point and zero at all other nodes. How can I choose four lines such that the eleventh shape functions vanishes on all other points? I can choose this line, I can choose this line, I can choose this line and I can choose this

line. So the shape function should vanish on this line, in this line and this line and this line. Looking at the equations of these lines and multiplying them together, I will get the fourth order shape function corresponding to the eleventh point. I can keep on constructing the higher order approximations to any order that I wish by using this kind of a structure. It can be done in the master element and immediately used.

We are now, in principle, in a position to construct any triangular Lagrangian basis function of any order that we wish to obtain. And the beauty of these basis functions is that we have exactly the number of functions that we need to have a complete definition of the polynomial of the given order.

(Refer Slide Time: 17:31)

Now we are going to go to another family of shape functions or basis functions, which are very popular and are probably used more than triangles. Let us look at rectangular elements. Instead of meshing the simple domain that I had taken earlier with triangles, I have meshed it with rectangles such that the size here is  $h_1$  and the size here is  $h_2$ .

Let us take a generic element here. This is element 1, 2, 3, and 4. So the rectangular element will have four corner nodes or four corner vertices. Everything has to be done or defined with respect to these corner vertices. The simplest thing we can do is to take a generic rectangular element.

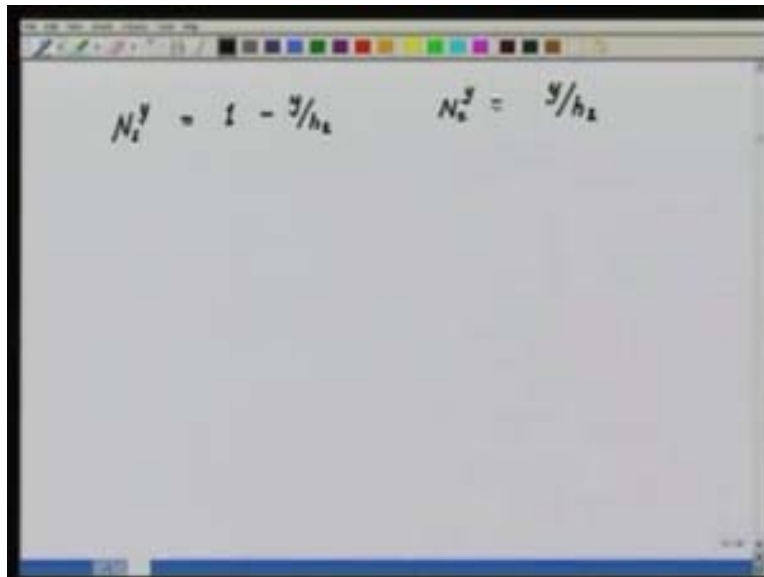

For simplicity, I am taking the first one. I will give a coordinate axis here,  $x$  and  $y$ , such that the first node has point locations  $(0, 0)$ . This is the first node, second node, third node, fourth, fifth, sixth, seventh, eighth, and ninth.

I take these four nodes and I will have 1 for the element, 2 for the element, 3 for the element, and 4 for the element. So I am taking the first element and by 1, 2, 3 and 4 here I mean the local numbering, just like we did for the triangles. The coordinates here are going to be  $(0, 0)$ ,  $(h_1, 0)$ ,  $(h_1, h_2)$  and  $(0, h_2)$ . I am doing a counter clockwise numbering. What are the simplest basis functions or simplest element shape functions that we can define? They have to be defined with respect to these four vertices. Let us take this element apart because these angles are  $90^\circ$ .

Let us imagine I have taken these two edges apart - this edge and this edge. Let us say this edge is with the nodes 1 and 2 and this edge is with the nodes 1 and 4. On each of these edges, as we had said for triangles also, the shape functions should be such for the two-D domain that the projection on the edge becomes a one-D shape function.

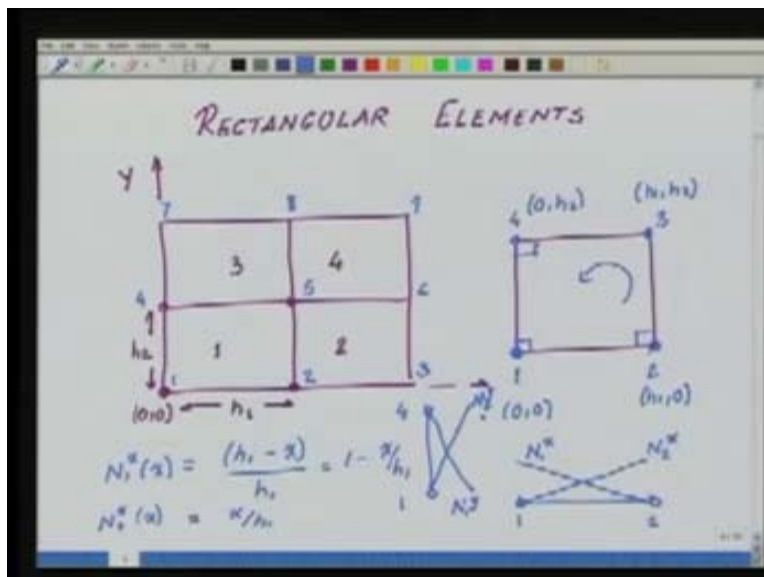

Let us take the same principle here. We have to define the shape functions in such a way that the projections on the edge become the one-D shape function. On this edge it will become this one-D shape function. Let us say these two linear are  $N_1$  of  $x$  and  $N_2$  of  $x$ . Similarly, here I will have this function. This will be  $N_1$  of  $y$  and this will be  $N_2$  of  $y$ . I have defined the linear on each of the edges. What is  $N_1$  of  $x$ ? As a function of  $x$  on this edge, it is quite easy to define the shape function. It should vanish at this point. It should be equal to 1 here. I will define it as  $(h_1 - x)$  divided by  $h_1$ , which is  $1 - x/h_1$ . The second one,  $N_2$  of  $x$  as a function of  $x$  (because this is a one-dimensional shape functions and along this edge there will only be functions of  $x$ ), this will be equal to nothing but  $x$  divided by  $h_1$ .

(Refer Slide Time: 22:11)

Similarly,  $N_1$  of  $y$  should be 1 here, 0 here at the point  $y$  equal to  $h_2$ . By the same token, it becomes 1 minus  $y$  by  $h_2$  and  $N_2$  of  $y$  becomes  $y$  by  $h_2$ . This is the simple definition.

(Refer Slide Time: 22:43)

Using these one-D shape functions that we have defined along this line and along this line, we take the product of these functions to get all the functions. If I take the product of  $N_1$  of  $x$ , that is, the function on this line corresponding to this node and function on this line corresponding to

this node, which is  $N_1$  of  $y$ , by the definition of  $N_1$  of  $x$  and  $N_1$  of  $y$ , this function is 1 at this node and vanishes at this node, which means it vanishes at this node also. It satisfies all our constraints that the function should have a value 1 at this node and 0 at all other nodes. Similarly, I go to this node. This node lies as a second node on this line, so I take  $N_2$  of  $x$ . On this line, this is the first node and so I take  $N_1$  of  $y$  and by definition,  $N_1$  of  $y$  is going to vanish here and here;  $N_2$  of  $x$  is going to vanish here. So it vanishes at all other points and gives me a value 1 at the second.  $N_3$  of  $x$  lies as a second node of this line. So  $N_2$  of  $x$  and it lies as a second node of this line and  $N_2$  of  $x$  into  $N_2$  of  $y$  should do the job and the fourth one should be  $N_1$  of  $x$  into  $N_2$  of  $y$ .

(Refer Slide Time: 22:43)

$$N_1^y = 1 - \frac{y}{h_2} \quad N_2^y = \frac{y}{h_2}$$

$$N_1^x(x, y) = N_1^x(x) N_1^y(y) = (1 - \frac{x}{h_1})(1 - \frac{y}{h_2})$$

$$N_2^x(x, y) = N_2^x(x) N_1^y(y) \quad \frac{1 - \frac{x}{h_1} - \frac{y}{h_2}}{1 - \frac{x^2}{h_1 h_2}}$$

$$N_3^x(x, y) = N_1^x(x) N_2^y(y)$$

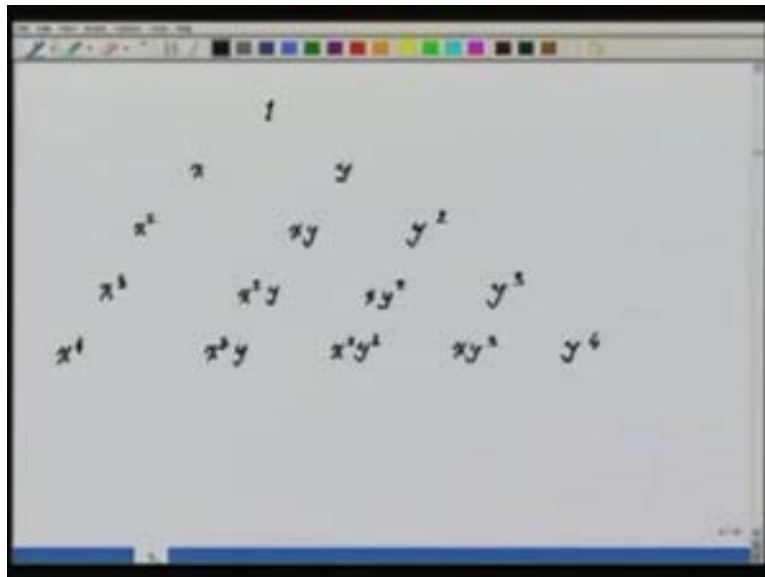

$$N_4^x(x, y) = \underline{N_2^x(x) N_2^y(y)}$$

TENSOR PRODUCT FAMILY OF SHAPE FUNCTIONS

We are going to define our shape functions in terms of this:  $N_1$ , which is a function in the element  $x$  and  $y$  in the element 1, equal to  $N_1$  of  $x$  into  $N_1$  of  $y$  which is the function  $y$ .  $N_2$  in the element 1 has a function of  $x$  and  $y$  is equal to  $N_2$  of  $x$  into  $N_1$  of  $y$ .  $N_3$  in an element 1 is equal to  $N_2$  of  $x$  which is a function of  $x$  into  $N_2$  of  $y$  which is the function of  $y$ .  $N_4$  in element 1 which is the function of  $x$  and  $y$  is equal to  $N_1$  of  $x$  and  $N_2$  of  $y$ . I have defined these four shape functions with respect to the four vertices of the rectangle and this is the minimum we can do, because these functions have to be defined by the logic that we have been following with respect to these four vertices. By definition, these are products of functions in the  $x$  direction and functions in the  $y$  direction. Since, they are defined as products of one-D functions defined in the  $x$  and  $y$  directions, they are said to be Tensor Product Family of shape functions.

Let us look at some features of it.  $N_1$  of  $x$  is nothing but  $1 - x$  by  $h_1$  and  $N_1$  of  $y$  is  $1 - y$  by  $h_2$ . So if I take this product, this is going to be  $(1 - x)(1 - y)$  plus  $xy$  by  $h_1 h_2$ . This part is linear in  $x$  and  $y$ . This part is bilinear, that is, it is not linear, it is more than linear in  $x$  and  $y$ . The basis functions or shape functions seem to represent more than the set of functions we need to represent completely or to define a linear. That is, they contain more terms than just the linear.

(Refer Slide Time: 27:33)

We have the Pascal triangle here:  $1, x, y, x^2, xy, y^2, x^3, x^2y, xy^2, y^3$ , (I will write up to the 4th order)  $x^4, x^3y, x^2y^2, xy^3$  and  $y^4$ .

(Refer Slide Time: 28:12)

$$N_1^y = 1 - \frac{y}{h_2} \quad N_2^y = \frac{y}{h_2}$$

$$N_1^x(x,y) = N_1^x(x) N_1^y(y) = (1 - \frac{x}{h_1})(1 - \frac{y}{h_2})$$

$$N_2^x(x,y) = N_2^x(x) N_1^y(y) = \frac{x}{h_1} (1 - \frac{y}{h_2})$$

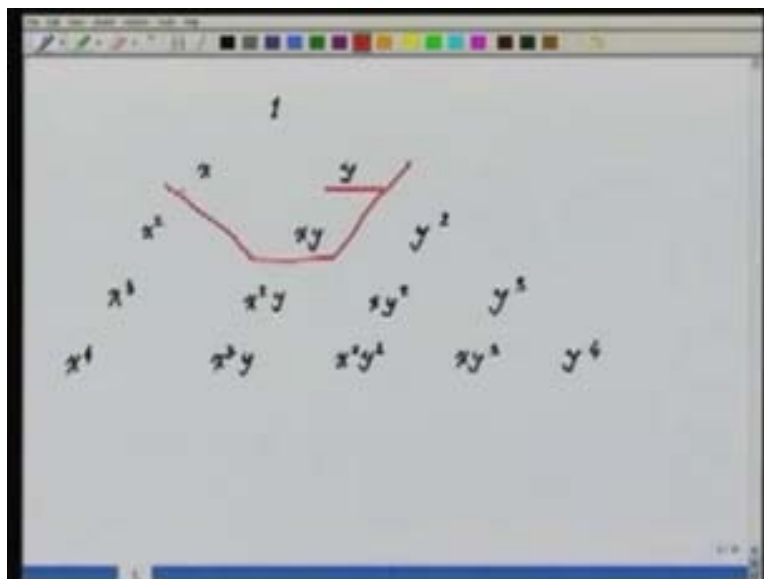

$$N_3^x(x,y) = N_2^x(x) N_2^y(y) = \frac{x}{h_1} \frac{y}{h_2}$$

$$N_4^x(x,y) = N_1^x(x) N_2^y(y) = (1 - \frac{x}{h_1}) \frac{y}{h_2}$$

TENSOR PRODUCT FAMILY OF  
SHAPE FUNCTIONS

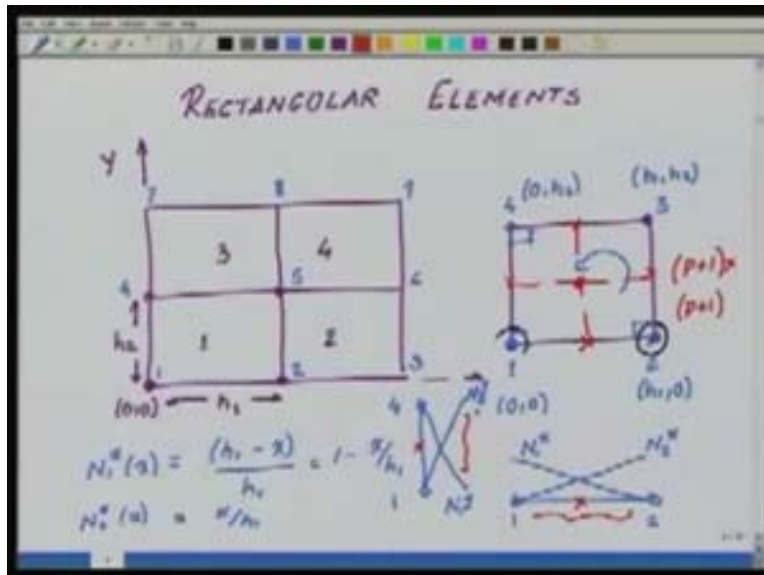

If I expand all of these functions  $N_1 N_2 N_3 N_4$ , I will find the same feature that they will contain the linear part in terms of 1, x and y plus they will also contain the product of x and y.

(Refer Slide Time: 28:26)

If I come to the Pascal triangle, what happens is, if I look at the representation of these functions, they will not only represent the linear, they will also contain the xy part. That is more than what is really required to define the linear polynomials.

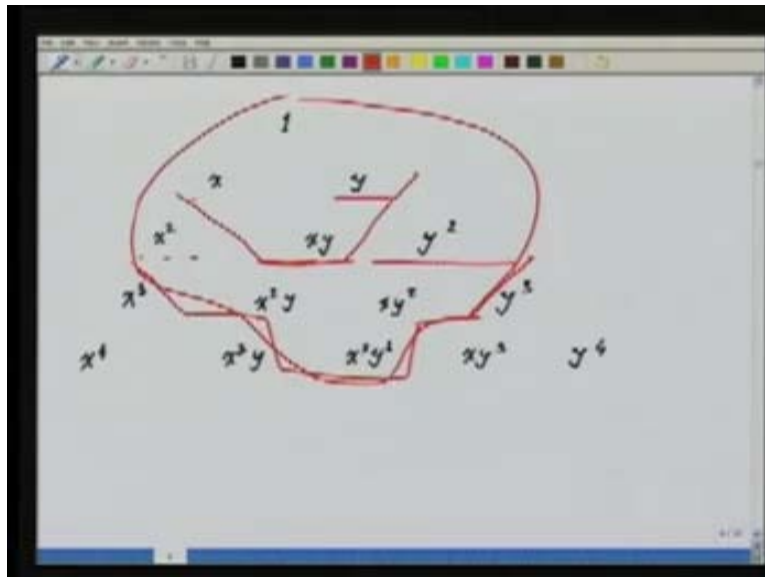

(Refer Slide Time: 28:52)

Similarly, if I define the quadratic shape functions, I will simply add intermediate points on each of these edges. We connect these points just like we had done for the triangles. I will get an additional node in the middle. There are nine such functions that are products: three functions on this edge, three functions on this edge; three into three and I have nine and these nine functions are nicely given here in terms of these nodal values. If these nine functions are to be given in terms of the quadratic, I will define the quadratic shape functions on the edge and multiply for the two edges to get the quadratic shape functions for the element.

Here the feature is that I get  $P+1$  functions in one direction into  $P+1$  functions in the other direction. That is, I will get  $P+1$  squared functions. For the linear I had 2 into 2 which is 4, for the quadratic I will have 3 into 3 which is 9, for the cubic I will have 4 into 4 which is 16. I am increasing the number of functions as I am increasing the approximation.

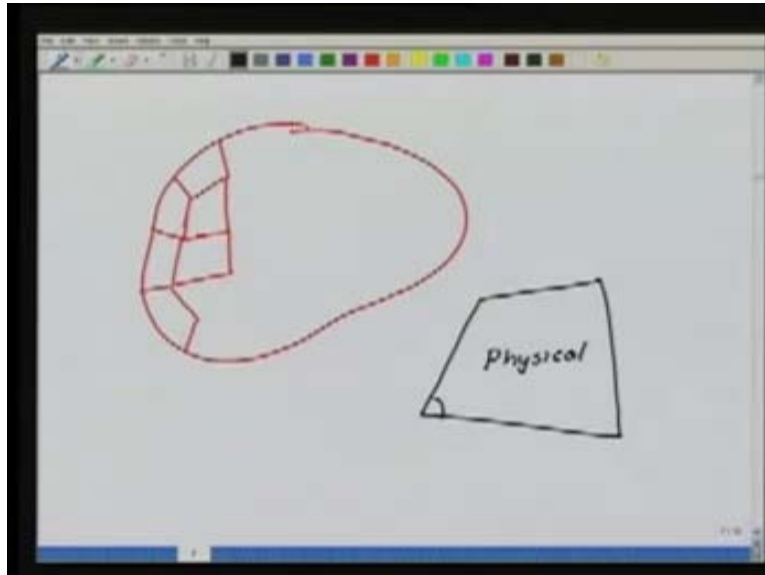

(Refer Slide Time: 30:30)

If we look at the quadratics by the same formula that we have followed, that is, the same line of approach, the quadratics should represent this much to be complete, but it turns out that they not only represent this much, they go and represent this whole set. That is, the quadratic definition will include all these functions. It will go beyond the quadratic and have these extra functions. These additional functions are also in the representation above the requirement of completeness. This is a feature of the Tensor Product Family.

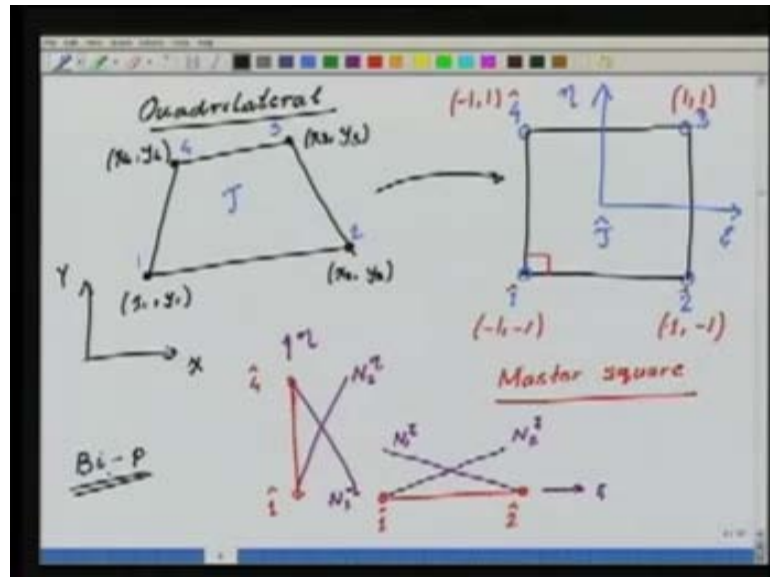

(Refer Slide Time: 31:25)

It is not always that we will have such a nice rectangular domain. Let us take this kind of a domain. If I try to mesh this domain with four noded entities, this mesh will have quadrilaterals. It will be a mesh of quadrilaterals, not of rectangles. When I have a mesh of quadrilaterals, then we do not have the luxury of having these two perpendicular edges for which we define these individual functions and take the product. I cannot do anything at the physical level, that is, at the level of the physical element.

For that we map this physical element to a master element. So we will have to define the master element now for these quadrilaterals. We define the master element in such a way that I can use this tensor product representation to get the shape functions in the master element.

(Refer Slide Time: 32:41)

Let us say this is the physical element, which is a generic quadrilateral, which has  $n$  nodes  $(x_1, y_1)$ ,  $(x_2, y_2)$ ,  $(x_3, y_3)$  and  $(x_4, y_4)$ . Let us say, I have the  $xy$  coordinate system somewhere. We are going to take it to a master element, which is defined as this. This is  $\psi$ . This is  $\eta$ . This is node 1 in the master element, node 2 in the master element, node 3 and node 4. This is the generic element  $\tau$ . This is the master element  $\tau$  hat and this is the node 1 in the physical element, node 2, node 3 and node 4.

Node 1 will have coordinates  $(-1, -1)$ . Node 2 will have coordinates  $(1, -1)$ . Node 3 will have coordinates  $(1, 1)$  and node 4 will have  $(-1, 1)$ . The four nodes in the master element – 1, 2, 3, 4, map to, let us say, 1 hat, 2 hat, 3 hat and 4 hat nodes with these coordinates. The master element is now a square and is called a master square.

How do I define the shape functions with the master element? The master element has edges that are perpendicular to each other. So I will take these edges out with the nodes 1 hat, 2 hat, 1 hat and 4 hat and then on these edges, I can redo the whole job as I had done earlier. I will define these linear functions on this edge, which is in the direction  $\psi$ , on this edge, which is in the direction  $\eta$ . I will define this linear again.

This is  $N_1$  psi. This is  $N_2$  psi. This is  $N_1$  eta. This is  $N_2$  eta. This way I can define these one-D shape functions on the psi edge and the eta edge. In terms of the products of these one-D shape functions, the shape function for the master element can be defined. If I have to define the bilinear or the linear approximation, it is a tensor product and it is called Bi-P approximation. Which means, it is P in one direction and P in the other direction. It is a product of these two Ps.

(Refer Slide Time: 36:38)

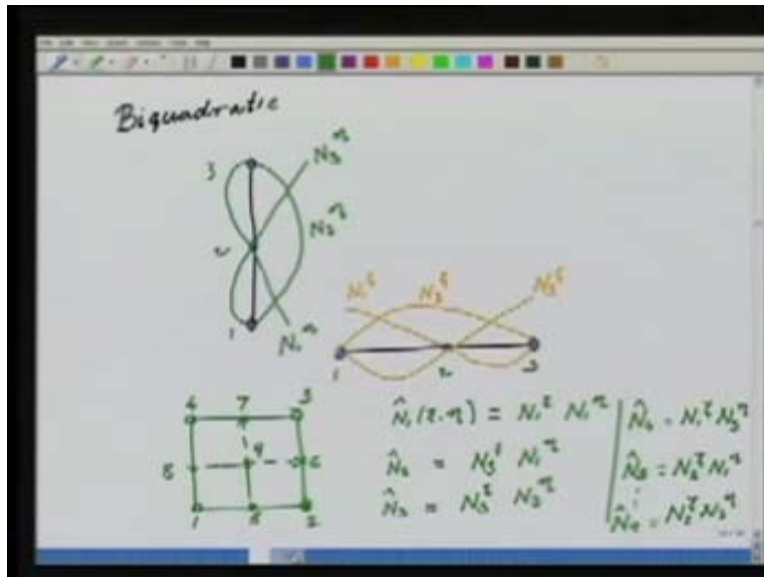

The image shows a whiteboard with four equations defining bilinear shape functions  $\hat{N}_i(\xi, \eta)$  as the product of one-dimensional shape functions  $N_i^\xi$  and  $N_i^\eta$ . The equations are:

$$\begin{aligned} \hat{N}_1(\xi, \eta) &= N_1^\xi N_1^\eta = \frac{1}{4}(1-\xi)(1-\eta) \\ \hat{N}_2(\xi, \eta) &= N_2^\xi N_1^\eta = \frac{1}{4}(1+\xi)(1-\eta) \\ \hat{N}_3(\xi, \eta) &= N_2^\xi N_2^\eta = \frac{1}{4}(1+\xi)(1+\eta) \\ \hat{N}_4(\xi, \eta) &= N_1^\xi N_2^\eta = \frac{1}{4}(1-\xi)(1+\eta) \end{aligned}$$

Below the equations, a horizontal line is drawn, and the text "Bilinear Shape Functions" is written in a cursive style.

When P is equal to 1, it is called a bi-linear approximation.  $N_1$  hat, which is a function of psi and eta, will be nothing but  $N_1$  psi into  $N_1$  eta.  $N_2$  hat as a function of psi and eta is equal to  $N_2$  psi,  $N_1$  eta.  $N_3$  hat, which is a function of psi and eta, is  $N_2$  psi,  $N_2$  eta.  $N_4$  hat psi and eta is equal to  $N_1$  psi into eta. We can define the bi-linear shape functions here. It will turn out to be 1/4th of (1 minus psi) into (1 minus eta). This one will be 1/4th of (1 plus psi) into (1 minus eta). This one will be 1/4th of (1 plus psi) into (1 plus eta) and this will be 1/4th of (1 minus psi) into (1 plus eta). So this way, I can define the bi-linear shape functions for the master element. Similarly, we can define the quadratic shape functions by quadratic shape functions.

(Refer Slide Time: 38:27)

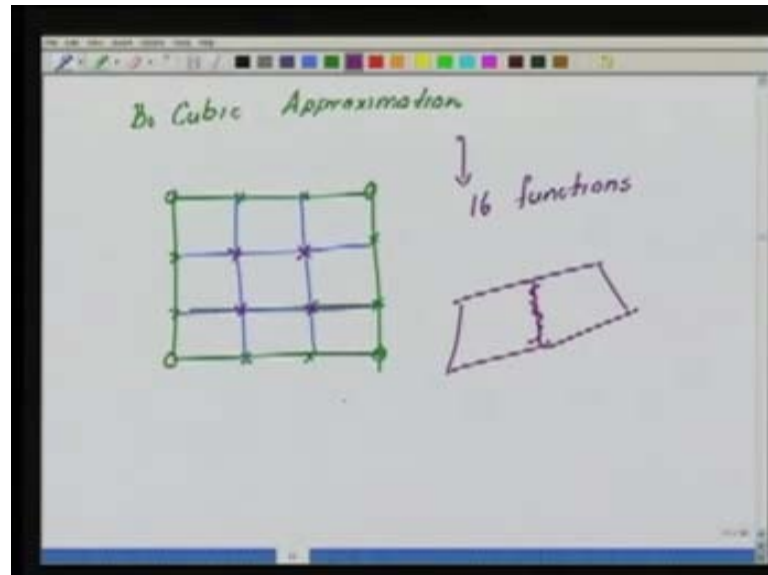

Let us look at biquadratics. As we had done earlier, this is the psi edge. This is the eta edge. I will add these additional nodes on the edge at the mid side and I will define these one-D quadratic functions on the edge. This becomes  $N_1$  psi. This becomes  $N_2$  psi. This becomes  $N_3$  psi. On the eta edge, I will similarly define  $N_1$  eta,  $N_2$  eta and  $N_3$  eta. I have three functions on each edge. So I have these nine functions defined on the master element with respect to these nine points. I will call this point 1, this is 2, this is 3, this is 4, and this is 5, 6, 7, 8 and 9. Depending on which line the point lies on, I will find the corresponding shape function.

For example,  $N_1$  hat as a function of psi and eta should be equal to (it has the first node of the psi side, first node of the eta side)  $N_1$  psi into  $N_1$  eta. Similarly,  $N_2$  hat, lies on the third node of the psi side and the first node of the eta side. So it will become  $N_3$  psi into  $N_1$  eta. To define  $N_3$  hat: ( $N_3$  hat lies on the third node of the psi side and the third node of the eta side)  $N_3$  psi into  $N_3$  eta.  $N_4$  hat is equal to  $N_1$  psi into  $N_3$  eta. Similarly  $N_5$  will be equal to (see it is a second node for the psi side and first node for the eta side)  $N_2$  psi into  $N_1$  eta.

To get  $N_9$  hat:  $N_9$  hat is equal to (it lies on the second node of the psi side and second node of the eta side)  $N_2$  psi into  $N_2$  eta. I am able to define all the nine basis functions with respect to these definitions of  $N_1$   $N_2$   $N_3$  and so on, depending on P on the edge.

Similarly, I can construct bi cubic approximation. If I look at the master element, I will have these corner vertices. On this edge I will have two more equally spaced points, just like we had done in the triangles. Connect these by lines. We will get four more points lying in the interior and we will get a grid of sixteen points. Bi Cubic will have sixteen functions. We can continue this to whatever order we want.

Constructing this basis functions in the generic quadrilateral element has to be done at the master element level and we follow the same principle that we had followed for the rectangular element and we get the shape functions. Question is will it give me a continuous approximation? Answer is yes, because, if I have the next element setting here and if I have two elements like this, the shape functions of both these elements should become equivalent to the one-D shape function on the edge. Both these functions on this edge will match from either side because they have to become equivalent to the same one-D shape functions. The approximation will match because the functions match. Continuity is not a problem here in this definition.

(Refer Slide Time: 44:46)

We have not discussed how we map this quadrilateral to the master element. What is the kind of mapping that gives me this? This is a domain with straight edges. For the mapping of the geometry, in this case, as long as I do not have curved elements, we are going to use bilinear map. That is,  $x$  at any point  $\xi$  and  $\eta$  in the master element will be sum of  $i$  is 1 to 4,  $x_i M_i$  (I am deliberately writing it as  $M_i$ ) as a function of  $\xi$  and  $\eta$ ,  $y$  as a function of  $\xi$  and  $\eta$  is sum  $i$  is 1 to 4,  $y_i M_i$  as a function of  $\xi$  and  $\eta$ . Where are these  $x_i$ s,  $y_i$ s? This is the  $(x_i, y_i)$ , this is  $(x_1, y_1)$ ,  $(x_2, y_2)$ ,  $(x_3, y_3)$  and  $(x_4, y_4)$ .

Why have I written  $M_i$ ? Because I want to bring out clearly that mapping need not always be of the same order as the approximation. Here, Irrespective of whether I am using a cubic approximation or a fourth order, that is, bi cubic or bi quadratic, the mapping is always going to be bilinear for this kind of a domain, where the quadrilateral is a straight edged quadrilateral. So the mapping should always be done with respect to the bilinear shape functions, while the approximation can be done with respect to any shape function that I wish. These  $M_i$ s are nothing but the bilinear shape functions.

(Refer Slide Time: 47:45)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it lists the partial derivatives:  $\frac{\partial x}{\partial \xi}$ ,  $\frac{\partial x}{\partial \eta}$ ,  $\frac{\partial y}{\partial \xi}$ , and  $\frac{\partial y}{\partial \eta}$ . Below this, the coordinate transformation is given as:  $x = x_1 \cdot \frac{1}{4} (1-\xi)(1-\eta) + x_2 \cdot \frac{1}{4} (1+\xi)(1-\eta) + x_3 \cdot \frac{1}{4} (1+\xi)(1+\eta) + x_4 \cdot \frac{1}{4} (1-\xi)(1+\eta)$ . The next line shows the partial derivative of x with respect to xi:  $\frac{\partial x}{\partial \xi} = -\frac{x_1}{4} (1-\eta) + \frac{x_2}{4} (1-\eta) + \frac{x_3}{4} (1+\eta) - \frac{x_4}{4} (1+\eta) = \frac{1}{4} [(x_2 - x_1 + x_3 - x_4) + \eta (x_1 - x_2 + x_3 - x_4)]$ . The final line shows the partial derivative of x with respect to eta:  $\frac{\partial x}{\partial \eta} = -\frac{x_1}{4} (1-\xi) - \frac{x_2}{4} (1+\xi) + \frac{x_3}{4} (1+\xi) + \frac{x_4}{4} (1-\xi) = \frac{1}{4} [(x_3 + x_4 - x_1 - x_2) + \xi (x_1 - x_2 + x_3 - x_4)]$ .

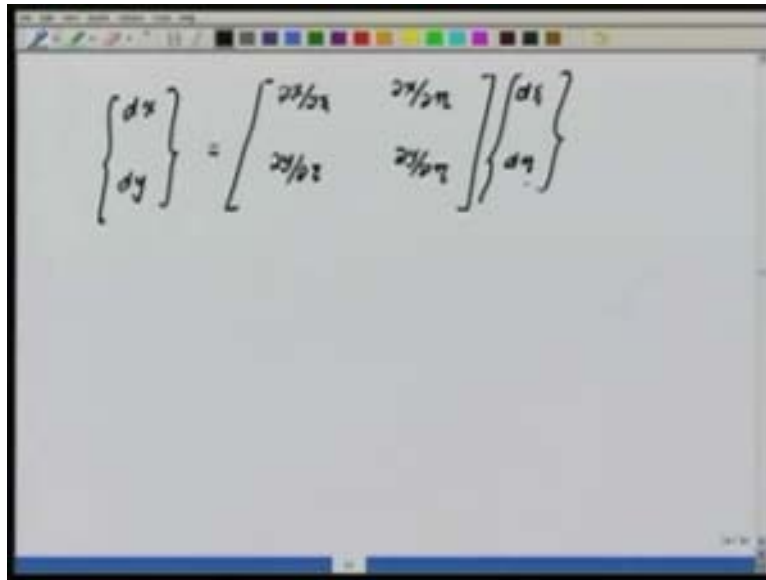

We see that as far as our computations are concerned, we finally want to put everything in a computer program. As far as the computations are concerned, we need quantities like del x divided by del psi, del x divided by del eta, del y divided by del psi and del y divided by del eta because, we have converted, we have mapped all our functions from the physical domain to the master domain. So why not do all the integration and other procedures which are required to get the stiffness matrices and the load vectors in the master element? These quantities are required. How do I find these quantities?

X will be equal to  $x_1$  into  $\frac{1}{4}$  of (1 minus psi) into (1 minus eta) plus  $x_2$  into  $\frac{1}{4}$  of (1 plus psi) into (1 minus eta) plus  $x_3$  into  $\frac{1}{4}$  of (1 plus psi) into (1 plus eta) plus  $x_4$  into  $\frac{1}{4}$  of (1 minus psi) into (1 plus eta). y is also written similarly, in terms of the y. So these are our Ms -  $M_1$ ,  $M_2$ ,  $M_3$  and  $M_4$ .

Del x divided by del psi becomes equal to minus  $x_1$  into (1 minus eta) by 4 plus  $x_2$  into (1 minus eta) by 4 plus  $x_3$  into (1 plus eta) by 4 minus  $x_4$  into (1 plus eta) by 4. So this one will be equal to, if I write it in terms of psi and eta,  $\frac{1}{4}$ <sup>th</sup> of (collect all the constant parts) ( $x_2$  minus  $x_1$  plus  $x_3$  minus  $x_4$ ) plus eta into ( $x_1$  minus  $x_2$  plus  $x_3$  minus  $x_4$ ). Similarly, del x divided by del eta is equal to minus  $x_1$  into (1 minus psi) by 4, minus  $x_2$  into (1 plus psi) by 4, plus  $x_3$  into (1 plus psi) by 4, plus  $x_4$  into (1 minus psi) by 4. If I collect, it will be  $\frac{1}{4}$  into (( $x_3$  plus  $x_4$  minus  $x_1$  minus  $x_2$ ) plus psi into ( $x_1$  minus  $x_2$  plus  $x_3$  minus  $x_4$ )).

I can get the quantities corresponding to y by replacing this by y and replacing this by  $y_1, y_2$  and so on. Similarly, I replace this one by y and these by  $y_1, y_2$  and so on. So  $\frac{dx}{d\psi}$ ,  $\frac{dx}{d\eta}$ ,  $\frac{dy}{d\psi}$ ,  $\frac{dy}{d\eta}$  can be now obtained. Once I have obtained these quantities, I use them to get the matrix of the transformation.

(Refer Slide Time: 52:12)

$$\begin{Bmatrix} dx \\ dy \end{Bmatrix} = \begin{bmatrix} \frac{\partial x}{\partial \psi} & \frac{\partial x}{\partial \eta} \\ \frac{\partial y}{\partial \psi} & \frac{\partial y}{\partial \eta} \end{bmatrix} \begin{Bmatrix} d\psi \\ d\eta \end{Bmatrix}$$

I would like to write  $dx, dy$  is equal to  $(\frac{dx}{d\psi}, \frac{dx}{d\eta}, \frac{dy}{d\psi}, \frac{dy}{d\eta})$  into  $(d\psi, d\eta)$ .

(Refer Slide Time: 52:42)

$$\frac{\partial x}{\partial \xi}, \frac{\partial x}{\partial \eta}, \frac{\partial y}{\partial \xi}, \frac{\partial y}{\partial \eta}$$

$$x = x_1 \frac{1}{4} (1-\xi)(1-\eta) + x_2 \frac{1}{4} (1+\xi)(1-\eta) + x_3 \frac{1}{4} (1+\xi)(1+\eta) + x_4 \frac{1}{4} (1-\xi)(1+\eta)$$

$$\frac{\partial x}{\partial \xi} = -\frac{x_1}{4}(1-\eta) + \frac{x_2}{4}(1-\eta) + \frac{x_3}{4}(1+\eta) - \frac{x_4}{4}(1+\eta) = \frac{1}{4} [(x_2 - x_1 + x_3 - x_4) + \eta(x_1 - x_2 + x_3 - x_4)]$$

$$\frac{\partial x}{\partial \eta} = -\frac{x_1}{4}(1-\xi) - \frac{x_2}{4}(1+\xi) + \frac{x_3}{4}(1+\xi) + \frac{x_4}{4}(1-\xi) = \frac{1}{4} [(x_3 + x_4 - x_1 - x_2) + \xi(x_1 - x_2 + x_3 - x_4)]$$

If I go back and look at this one, I can write this expression as  $A_1$  plus  $A_2$  eta and this expression becomes  $B_1$  plus  $B_2$  psi.

(Refer Slide Time: 53:08)

$$\begin{Bmatrix} dx \\ dy \end{Bmatrix} = \begin{bmatrix} \frac{\partial x}{\partial \xi} & \frac{\partial x}{\partial \eta} \\ \frac{\partial y}{\partial \xi} & \frac{\partial y}{\partial \eta} \end{bmatrix} \begin{Bmatrix} d\xi \\ d\eta \end{Bmatrix}$$

$$|J| = \frac{\partial x}{\partial \xi} \frac{\partial y}{\partial \eta} - \frac{\partial x}{\partial \eta} \frac{\partial y}{\partial \xi}$$

$$= (A_1 + A_2 \eta)(D_1 + D_2 \xi) - (B_1 + B_2 \xi)(C_1 + C_2 \eta)$$

$$= \bar{A}_1 + \bar{A}_2 \xi + \bar{A}_3 \eta + \bar{A}_4 \xi \eta$$

$$|J| > 0$$

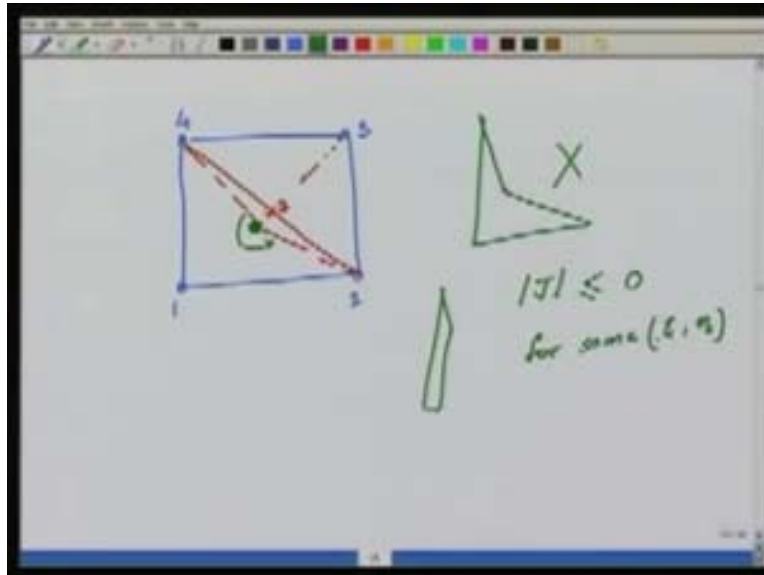

This one is going to be  $C_1$  plus  $C_2$  eta and this one is going to be  $D_1$  plus  $D_2$  psi. Now I have to compute the Jacobian, because Jacobian is needed for the transformation of the integrals from the physical domain to the master domain. This will be equal to (del x divided by del psi into del

$y$  divided by  $d\eta$ ) minus ( $d x$  divided by  $d\eta$  into  $d y$  divided by  $d\psi$ ).  $d x$  divided by  $d\psi$  is  $A_1$  plus  $A_2 \eta$ . This one is  $D_1$  plus  $D_2 \psi$ , where the  $D_1, D_2$  are again obtained from the previous expression.  $d x$  divided by  $d\eta$  is  $B_1$  plus  $B_2 \psi$  and the second one is going to be  $d y$  divided by  $d\psi$ , that is,  $C_1$  plus  $C_2 \eta$ .

In the product, it will be  $A_1 \bar{A}$  plus  $A_2 \bar{A} \psi$  plus  $A_3 \bar{A} \eta$  plus  $A_4 \bar{A} \psi \eta$ , where the bars are obtained like this for us:  $A_1 \bar{A}$  is  $A_1 D_1$  minus  $B_1 C_1$  and so on. The bottom line is that the Jacobian is no longer a constant. Even with this bilinear map, this is no longer a constant because it is now a function of  $\psi \eta$  and the product  $\psi \eta$ . While in the triangular element, when we did the linear map, the Jacobian turned out to be a constant.

When we have to do the numerical integration, we have to account for this part of the Jacobian. Jacobian is also a bilinear in terms of the  $\psi$  and  $\eta$  and because it is a bilinear in terms of  $\psi$  and  $\eta$ , we would like as such, that the Jacobian should always be greater than zero, because that is what is physical and that positive area maps to a positive area. It is not that the area can become negative or a given area cannot map to a point. An area will map to another area, but this will be a positive number, the ratio may be less than one or greater than one but nevertheless, it is a positive number and the ratio of the two areas is nothing but the Jacobian. When we say Jacobian is zero, it means the area maps to a point, to which we not aligned, we cannot have. It is unphysical. We would like to avoid elements, geometries of quadrilaterals for which this Jacobian can become a negative or zero at a point. Who stops this from becoming negative or zero? I can have some combinations of  $\psi$  and  $\eta$  given this  $A_1, A_2, A_3,$  and  $A_4$  that are the four nodal coordinates, and will define  $A_1 \bar{A}, A_2 \bar{A}, A_3 \bar{A}, A_4 \bar{A}$  in such a way that the Jacobian could be negative at a point.

(Refer Slide Time: 56:44)

It is quite easy to show that this can only happen, when (let us take this as the initial physical element) I have 1, 2, 3, 4, these four points and I decide to start moving point 3 inwards. It will turn out that point 3 could lie on a triangle, degenerate triangle. If I go beyond this, that is, if point 3 moves to this point here, then the Jacobian would be negative at some points. Geometries of quadrilaterals for which one of the angles becomes an obtuse angle are not allowed.

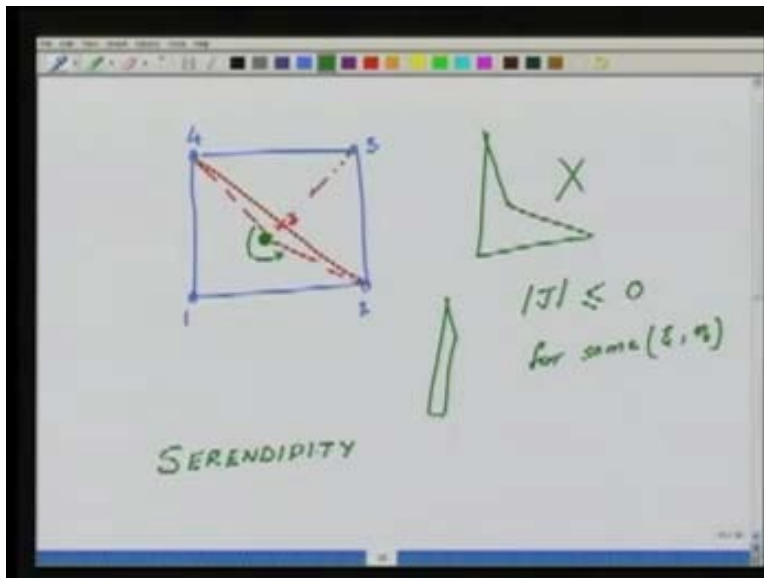

One has to be very careful when making the mesh and ensure one does not get this kind of a quadrilateral domain. We can always convert it into two quadrilaterals for which the quadrilateral is convex, that is, the angle is certainly lesser than or equal to 180 degrees. We do not want quadrilaterals for which angles are large. We should not have these kinds of quadrilaterals – very large or very small. In general their performance will be pretty bad. So while making the mesh we have to ensure that these quadrilaterals are as good as possible. The angles are not too large and the angles are not too small. In this case, we will have a point where Jacobian is less than or equal to 0 for some  $\xi$  and  $\eta$ . This is a very important point that has to be kept in mind, when we are using quadrilateral elements.

(Refer Slide Time: 59:00)

As far as the definition of the quadrilateral is concerned, these rectangular elements, we have over-done the job. That is, we have in the Pascal triangle, accounted for more terms. The question is can we redefine our basis functions or the shape functions over the quadrilateral in such way that we do not over-do the job. That is, can we cut out some of these extra terms?

(Refer Slide Time: 59:25)

The answer is yes. That comes by using what we call the ‘serendipity family of functions’. Completeness is guaranteed and these extra terms are cut down.

So in the next class, as far as the approximation is concerned, we are going to discuss the serendipity family of shape functions. Then we are going to now consolidate everything in terms of the finite element approximation in an element. We will then move on to look at how we are going to use this in a computational regime. That is, how numerical integrations are done for the quadrilateral or for the triangular element.
