Module - 02

Lecture - 10

Welcome to this module 10 on Manufacturing Systems Technology, a quick recap of the last module.

(Refer Slide Time: 00:15)

Review of Previous Lecture

- Non-parametric representation of equation (Implicit case).
- Parametric equation based representation of an ellipse.
- Parametric representation of synthetic curves.
- Concepts of continuity.
- Various fits. (Hermite Cubic Spline, Bezier, B-Spline, Rational and non uniform rational B-spline fit)

We were talking about or discussing about the non parametric representation of equations of a straight line followed by an ellipse. And then, we discussed about the implicit case, in which an ellipse can be represented or formulated a parametric equation in terms of an angle α , which varies between 0 and 360 degrees. And then, basically also talked about how a complex topology can be split up into different synthetic curves with a precedence relationship between the different elements of the curve and discussed concepts of continuity in this particular module.

Further I mentioned that probably, today I am going to talk over a little bit details about how this fits of the various sections of the curves can be made and also how the variation

of the curves along a certain domain, a local domain can be made by changing the different parameters related to the fit that is in question.

(Refer Slide Time: 01:06)

Hermite Cubic Spline

Basic function \rightarrow Cubic polynomial (Parametric Equation)

\rightarrow Develop the equation which will involve some parameter = t

\rightarrow To fit the equation that has been developed to certain conditions which can be mapped directly from the topology that you are wanting to fit.

$v(t) = a_0 + a_1 t + a_2 t^2 + a_3 t^3$ (1)

where $0 \leq t \leq 1$ is the parameter

$v(0), v(1), v'(0), v'(1) \rightarrow$ why? (A) $v(0)$
Ex: $\begin{bmatrix} a_0 \\ a_1 \\ a_2 \end{bmatrix}$

$v'(t) = a_1 + 2a_2 t + 3a_3 t^2$ (2)

$t=0$	$v(0) = a_0$	$v'(0) = a_1$
$t=1$	$v(1) = a_0 + a_1 + a_2 + a_3$	$v'(1) = a_1 + 2a_2 + 3a_3$

So, let us look at the Hermite cubic Spline fit or how to plot a Hermite cubic Spline curve. So, what are the basic assumptions in such a system? The first thing that we probably need to find out is the basic function, which in this case turns out to be a cubic polynomial. Obviously, what we are proposing is a sort of a parametric equation, which is more flexible as you have seen before that you can really vary it over a local domain given a certain global range within, which the curve is there.

And, what are all this needed is that first of all we need to sort of develop, the equation which will involve some parameter. Let us say we call this parameter t , which will have a cubic form of course, and the next step is to fit the equation that has been developed to certain conditions, which can be mapped directly from the topology that you are wanting to fit. So, let us say we have an equation a cubic polynomial function $v(t)$ equals a_0 plus $a_1 t$ plus $a_2 t^2$ plus $a_3 t^3$, where t varying between 0 and 1 is the parameter.

The Hermite cubic Spline tries to define the curve being estimated more meaningfully in terms of certain end conditions and these n conditions can match with the conditions of the topology that you would like to map. In this particular case, it so happens that, the basic premise is that the curve; that is being formulated between two such points, let us

say A and point B on the topology corresponding to the parameter t equal to 0 and a function v , which has been indicated here and v_1 .

So, in a way on the topology if you have a xyz coordinate system you can plot, what really is the x and y dimensions or coordinates on that topology and this can be mapped by any measuring system like CMM etcetera. And then, also these slopes at both the ends, which are important for formulating this particular fit, we call it v_0 and v_1 . So, the n conditions which are more like measurable conditions are the points along both the ends, which you need to fit and the slopes at those points, which are sort of the global domain for the whole curve starting between A and B as can be seen in this particular figure.

So, how do we develop this connectivity or how do we develop this set of you know different points, which gives this cubic relationships between the point A and the point B on the topology is the main question. So; obviously, the n conditions that we probably need to use are v_0 , v_1 , v_0 and v_1 . Why are we choosing these n conditions also is quite important and it has to be addressed. So, let us look at that how we can really do a curve fitting of this particular equation.

So, the best idea is to be able to keep on varying t between 0 and 1 as has been illustrated here and try to find out, what are these different parameters a_0 , a_1 , a_2 and a_3 given the end conditions, which are already known to you. So, v_0 , which is the end which is representing the end A is corresponding to some coordinate point x_a, y_a and let us say this is measurable data from coming out of some CMM or something.

Similarly, x_b, y_b some coordinate point and you know the slopes are also the measurable data at both the ends of the topology. We will come back to address this issue that how difficult it is to really measure the slope and one of the reasons why Hermite Cubic Spline fit may not be preferred in comparison to some other fits like Bezier etcetera, where only the end points are needed and the variations are needed to sort of map the topology.

So, here let us say we first of all try to calculate the v_t , which is essentially $1 + 2a_2 t + 3a_3 t^2$. And then, we try to put the n conditions corresponding to t equal to 0 and t equal to 1 and find out, what are the different n conditions. We already know the set x_a, y_a , which is corresponding to the n condition v_0 . Similarly the set $x_b,$

yb, which is corresponding to the n condition v 1 and this data is as I told you earlier measured data, which can be used for fitting to that topology, which you are measuring this particular piece of the curve synthetic curve.

So, here v dash 0 is actually equal to a 1 and v 0 from this equation you know, let us say equation 1 and equation 2, the v 0 is equal to a 0. And similarly, if we go on the other side and do v 1, v 1 comes out to be equal to a 0 plus a 1 plus a 2 plus a 3 and similarly, v dash 1 comes out to be equal to a 1 plus twice a 2 plus thrice a 3. So, at the two n conditions corresponding to t equal to 0 and corresponding to t equal to 1, we have now sort of four equations, where mind you this v 0, v dash 0, v 1 and v dash 1 they are all known variables.

So, the v 0, v dash 0, v 1 and v dash 1 they are all known variables and we want to represent the unknowns, which are the a 0 to a 3 in terms of the known variables. So, what we do is we try to solve these equations, which have been formulated, these are linear equations.

(Refer Slide Time: 09:19)

Derivation of the parameter equation

$$a_0' = v(0), \quad a_1' = v'(0)$$

$$a_2' = 3[v(1) - v(0)] - 2v'(0) - v'(1)$$

$$a_3' = 2[v(0) - v(1)] + v'(0) + v'(1)$$

Substitute the 90N94 back into our cubic polynomial function

$$v = v(t) = \frac{v(0)[1-3t^2+2t^3] + v'(0)[3t^2-2t^3] + v'(1)[t-2t^2+t^3]}{+v'(1)[-t^2+t^3]} \quad \text{--- (1)}$$

$$\textcircled{v} = \begin{bmatrix} 1 & t & t^2 & t^3 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -3 & 3 & -2 & -1 \\ 2 & -2 & 1 & 1 \end{bmatrix} \begin{bmatrix} v(0) \\ v'(0) \\ v'(1) \\ v'(1) \end{bmatrix}$$

And come up with a solution, which is written in a manner that a 0 is actually equal to v 0, a 1 equals v dash 0, a 2 equals thrice v of 1 minus v 0 minus twice v dash 0 minus v dash 1 and a 3 equals twice v 0 minus v 1 plus v dash 0 plus v dash 1. So, once these parameters a 0 to a 3 are known, we can actually substitute these back into our cubic polynomial

function, so that you could fit the particular polynomial to that topology which is in concern.

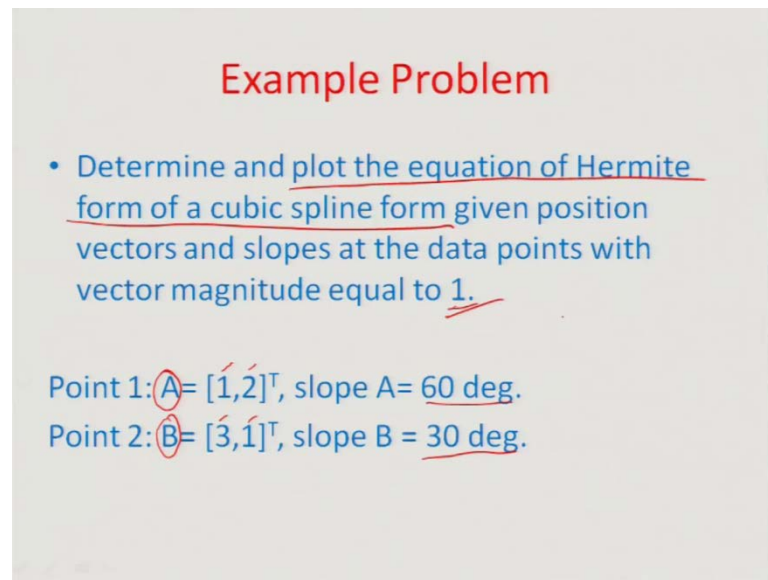

So, therefore, if the final polynomial can be written down as $v_0 + v_1 t + v_2 t^2 + v_3 t^3$ if I do some algebraic manipulation in a way that you know we assemble all the v_0 's or the coefficients with the v_1 's v_2 's v_3 's together. So, we have v_0 times of $1 - 3t^2 + 2t^3$ plus v_1 times of $3t - 2t^2 + t^3$ plus v_2 times of $t^2 - 2t^3$ plus v_3 times of t^3 as the main equation, which is the fitted equation.

In this particular case you can see that the n conditions v_0 , v_1 , v_2 , and v_3 are known again I am just sort of ascertaining this point and based on that you can develop an equation in cubic order, which can actually fit the real life surface of the real topology which is in particular question. So; obviously, we are doing a 2D mapping right now, but this can be extendable to the three dimension, where you also have the z component it will become a little more complex and we will take this up separately as a module.

But, if you are doing a two dimensional curve fit kind of a situation between two points it is very easy to go in this manner and formulate it fit. So, if I were to construct this equation for the r in terms of you know multiplying matrices we can say that r becomes equal to $1 + t + t^2 + t^3$ times of some kind of a basis matrix times of the values v_0 , v_1 , v_2 , and v_3 and this basis matrix if you lay this equation out in a proper manner equation one out in a proper manner and try to separate out the multipliers comes out to be $1, 0, 0, 0, 0, 0, 1, 0, -3, 3, -2, -1, 2, -2, 1, 1$.

So, that is how you can actually do a fit with this basis matrix a matrix, which has all the essential slopes and the n conditions the n slopes and the n coordinates and the of the vector comprising of the various orders of the parameter t and I would just like to illustrate it in the next module, how sort of in the next example problem that how you can actually do a curve fit, how such a fit can be made.

(Refer Slide Time: 13:46)

Example Problem

- Determine and plot the equation of Hermite form of a cubic spline given position vectors and slopes at the data points with vector magnitude equal to 1.

Point 1: $\mathbf{A} = [1, 2]^T$, slope A = 60 deg.
Point 2: $\mathbf{B} = [3, 1]^T$, slope B = 30 deg.

For example in this problem we want to determine and plot the equation of Hermite form of cubic Spline fit and we have been given position vectors and slopes at data points with vector magnitude is equal to 1. So, the data points are point A of point 1 corresponding to A on the curve that I had illustrated earlier the x and y values are 1 and 2. And similarly, at B the x and y values are 3 and 1; obviously, the slopes are also given to be 60 degrees and 30 degrees at both the n conditions.

So, in this manner we have to fit the equation that we had formulated earlier to these n conditions and then, we will try to physically plot them and see, what is really the variability of the surface aspect.

So, if you vary the different end conditions as you will see in this particular case mostly it is the magnitude of the slope that will vary the curve there would be a family of curves, which are generated and the idea is, then that whatever topological mapping is needed can be done by looking at the topology and looking at this variation in the local domain of the curve and several such synthetic curves are plotted in unison to one another, so that the whole surface can get mapped up, so we are going to do this particular plotting and mapping in the next module.

Thank you.
