Course Title
Basics of Finite Element Analysis

Lecture – 17
Variational Methods : Rayleigh Ritz Method

by
Prof. Nachiketa Tiwari
Dept. of Mechanical Engineering
IIT Kanpur

Hello, today is the fifth day of this course, welcome to the course and what we are going to discuss today is how different types of variational formulations and one of these particular formulations known as the Rayleigh Ritz method is very frequently used in finite element analysis, but we will not only discuss the Rayleigh Ritz approach but maybe in the next class or one or two other classes we will also discuss other approaches which are used to formulate our problems and the fundamental difference in all these formulations are is of two types.

First is that either we use the strong form or the weak form that is one difference, and the other difference is that what type of weight functions do we choose, so what we had discussed earlier was that the choice of weight functions is to be such that it has to meet, it has in context of weak formulation it should represent the variation in the dependent variable, in some formulations it is a little more restricted so we will discuss all these details things in detail.

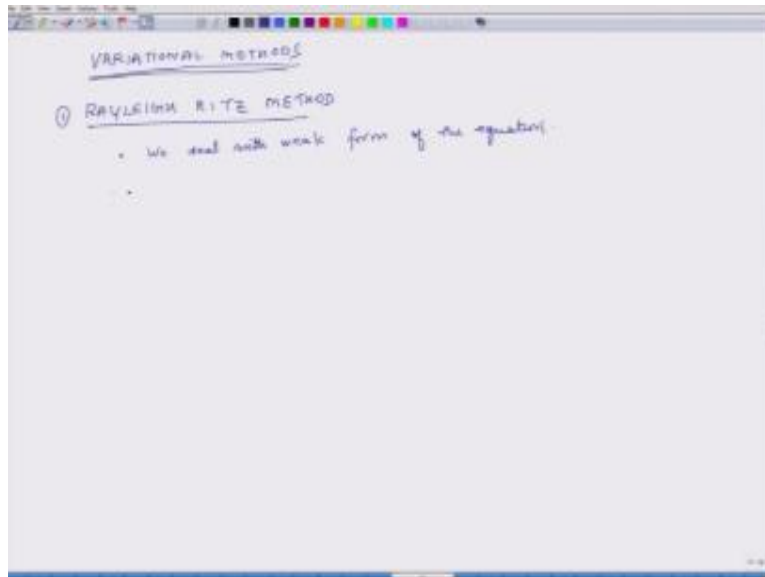

(Refer Slide Time: 01:37)

So we are going to discuss variational methods and till so far we have not come to the element level but maybe in one or two lectures once we have covered we have done an overview of different methods we will see that these methods which we are discussing can be applied either over the entire domain of the system or we can apply them at element level also, so we understand these methods then graduating from here to the element level and developing element level equations.

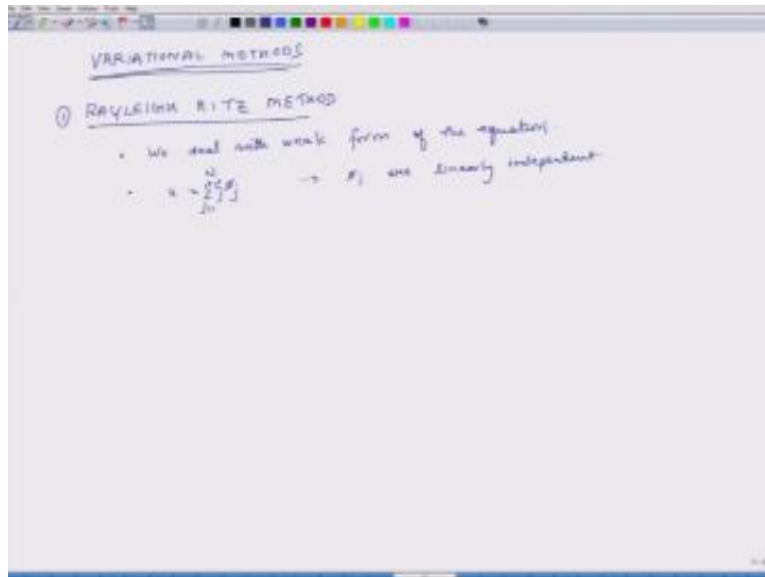

Is a fairly straightforward exercise so it is important that we understand the fundamental principles underlying these methods and then we will start working on the finite element formulation.

(Refer Slide Time: 02:26)

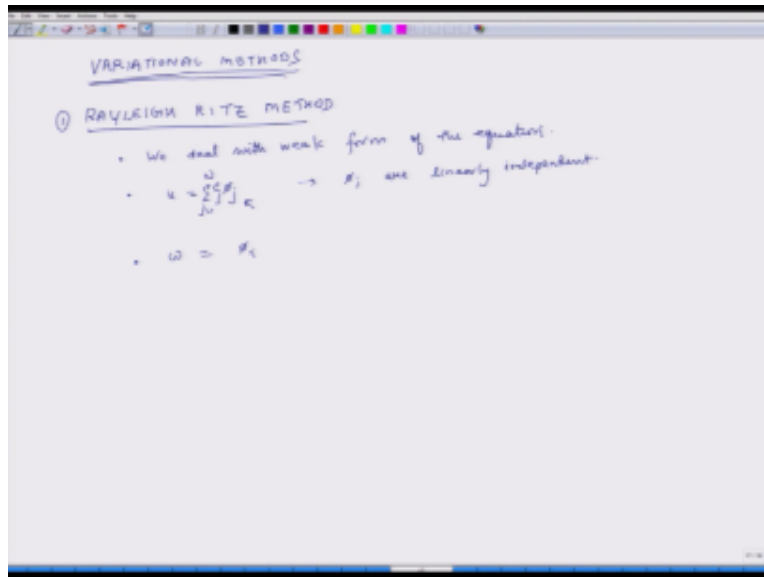

So, so the first method is known as Rayleigh Ritz method okay, and in this couple of important points that we only work on weak form, second is that when we pick \emptyset .

(Refer Slide Time: 03:19)

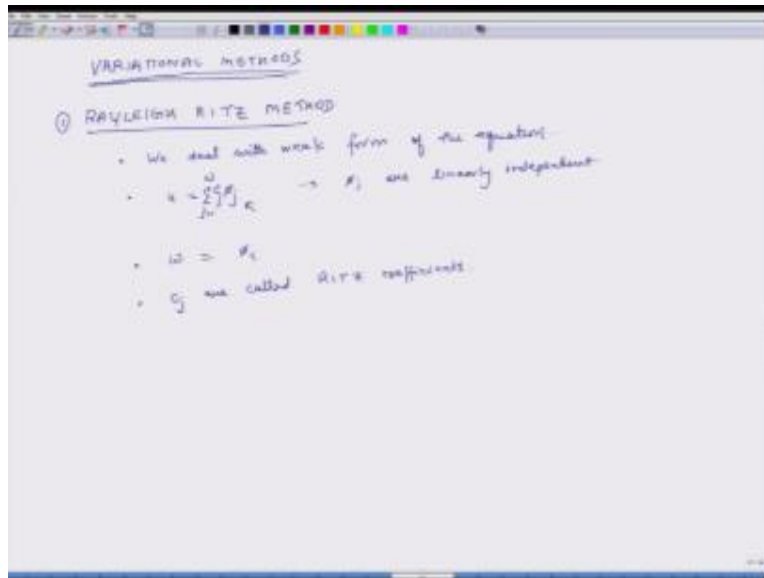

So we pick them in the way that u equals $\sum c_j \phi_j$, $j = 1$ to n and these ϕ_j are linearly independent, we cannot make up functions which are linear functions of others okay, otherwise you will get simultaneously, simultaneous equations and equations in n and unknowns, but when we will start solving it we will not be able to solve the solution unknowns.

(Refer Slide Time: 04:05)

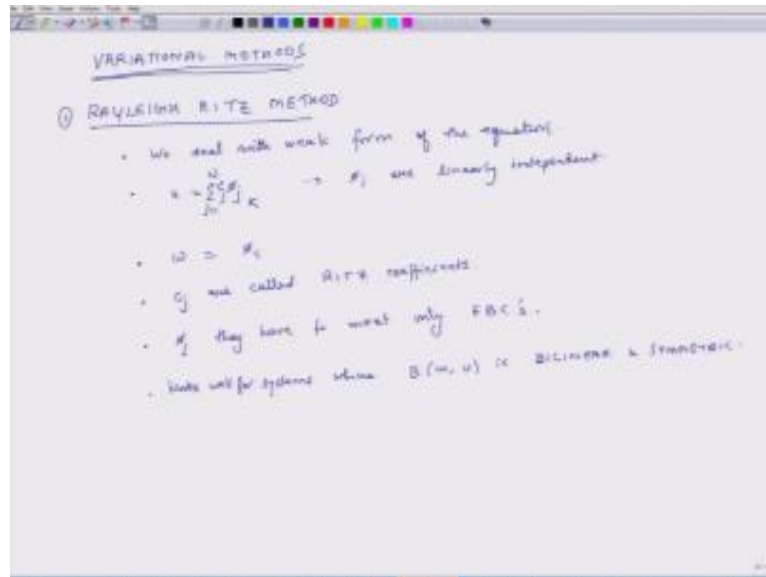

The 3rd thing is that in Rayleigh Ritz method w is nothing but ϕ_i so once we have made a choice on these ϕ_j it is essentially use the same functions in place of w okay, these C_j 's

(Refer Slide Time: 04:26)

Are called Ritz coefficients, all Ritz coefficients so if there are n unknowns I know that there are n weight functions also, we got the number of weight functions associated with n unknowns is also n , so I get n equations, n unknowns and I can solve them.

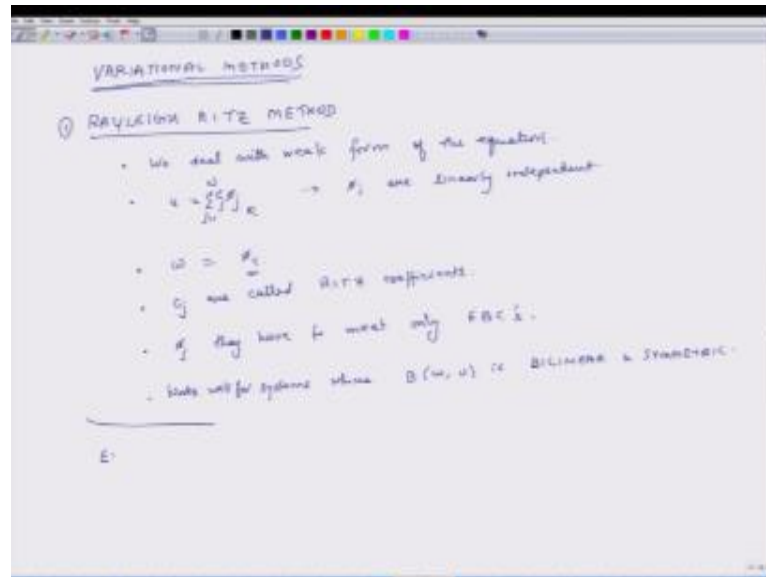

(Refer Slide Time: 04:58)

Further what we had discussed earlier in the in the last class and the class before that is that these functions ϕ_j they have to meet only essential boundary conditions, we do not have to worry too much about the natural boundary conditions because when we developed the weak form the natural boundary condition automatically comes into the equation and if its values is known we just plug in those values in the equation, and the last and very important point is that all this thing works well only for, for systems where this $B(w, u)$ is bilinear and symmetric.

I will not say it works only for but it works really well, works well for systems if it is not bilinear in symmetric then we may end up getting non linear equations in C , C 's so then we have to figure out how to solve them but for bilinear symmetric functionals represented by B_w it works really well and it is pretty straightforward, so we will discuss this further, so example.

(Refer Slide Time: 06:55)

So we had seen that in context of that bar that is one differential equation it can solve there may be others also it could be in general represented, represented as $B(w \text{ and } u)$ is equal to L of u , excuse me W and we say that d is bilinear and symmetric, so if that is the case then I can also represent the it has i equals $1/2$ of $B(u, u) - L$ of u and so this is the equation which I have to solve, this is the functional and if I minimize this functional I get this equation, we have seen this in the last class.

Because the variation in u is w so this is w okay, so now we assume that you and let us say that it this u is having n terms in its solution so that is why I call U_n so it is a n term solution C_j, ϕ_j is some constant okay, so I can, so let us call this equation, 1 call this 2, so if we put 1 in 2 what do I get I get, so u_n is this entire thing u is this thing and also w is no, no that is fine but what I am saying is I know that u is this equation represented by equation 2 and w is the weight function and I said that in Rayleigh Ritz the weight function is same so it could .

(Refer Slide Time: 09:22)

EXAMPLE

→ $B(u, v) = l(v)$ ① B - bilinear & symmetric

$I = \frac{1}{2} B(u, u) - l(u)$

$\delta I = 0$

Assume $u_h = \sum_{j=1}^n c_j \phi_j + \phi_0$ ②

Put ② in ①:

$B\left[\phi_0, \left(\sum_{j=1}^n c_j \phi_j + \phi_0\right)\right] = l(\phi_0)$ ③

Because B is bilinear,

$\sum_{j=1}^n B[\phi_0, \phi_j] c_j = l(\phi_0) - B(\phi_0, \phi_0)$ ④

N eqns
 N unknowns

$[B] \{c\} = \{F\}$

\downarrow Known \uparrow Unknown

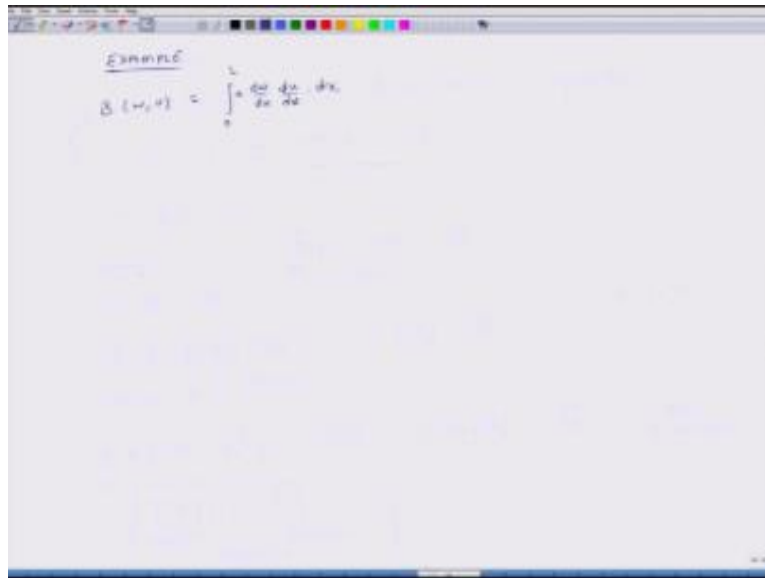

Unknown \downarrow

It is F_i so instead of w I am putting $f_i, c_j, \phi_j + f_0$, so this entire thing in parenthesis it represents u is equal to L of f_i , this is equation 3 and we will actually do one example right now, this is very general but we will actually do an example so you will see how this works out so because, because B is bilinear what I can do is that I can pull out C_j out of this bracket and we will actually do an example and we will see what that means so I can write it as summation of $j=1$ to n to e of f_i , okay, so because it is bilinear.

I can separate this F_0 separately and also because it is bilinear I can oh where did C_j go, C_j I can take C_j also out of the bracket, now when you look at this equation 4 you see that for different values of i so $j=1$ to n okay, for different values of i , this is one equation and on the in this J I am adding up everything right. So for different values of i , I will get different equations, if I put $F_i = F_{i1}$ I will get one equation, $f_i = f_{i2}$ I will get second equation and all these C_j s are unknowns so I will get n equations involving C_j 's which are n unknowns so I will get n equations.

And n unknowns okay, and essentially what I will get is a b matrix multiplied by a Vector C and this is equal to a vector f so this is known, this is unknown, and this is known okay, so now I can solve these equations and get the values of C_s .

(Refer Slide Time: 13:01)

EXAMPLE

$$B(u, v) = \int_0^1 \frac{du}{dx} \frac{dv}{dx} dx$$

So we will do an example, so this is which formulation the Rayleigh Ritz formulation okay, the main thing about Rayleigh Ritz formulation is its weak form, it uses weak form and here the choice of weight function the same as the choice of polynomial for you know approximation functions, so in context of the bar problem B we had seen it was defined as 0 to 1 dw over dx , du over dx times dx and there was this constantly or some parameter way okay, so what we will do is.

(Refer Slide Time: 13:46)

EXAMPLE

$\rightarrow B(u, v) = f(u)$ ① B is symmetric

$$I = \frac{1}{2} B(u, u) - f(u)$$

$\delta I = 0$

Assume $u = \sum_{j=1}^n c_j \phi_j + \phi_0$ ②

Put ② in ①:

$B\left[\phi_i, \left(\sum_{j=1}^n c_j \phi_j + \phi_0\right)\right] = f(\phi_i)$ ③

Because B is bilinear,

$$\sum_{j=1}^n B[\phi_i, \phi_j] c_j = f(\phi_i) - B(\phi_i, \phi_0)$$
 ④

11 eqns
 11 unknowns

$$\begin{bmatrix} \cdot \\ \cdot \\ \cdot \end{bmatrix} \begin{Bmatrix} c_1 \\ c_2 \\ \vdots \end{Bmatrix} = \begin{Bmatrix} F_1 \\ F_2 \\ \vdots \end{Bmatrix}$$

Unknowns Known

We will compute this b metrics for this type of a function.

(Refer Slide Time: 13:51)

EXAMPLE

$$B(u, v) = \int_0^L a \frac{\partial u}{\partial x} \frac{\partial v}{\partial x} dx$$

$$u = \sum_{j=1}^n \phi_j c_j \quad N=2$$

$$B(\phi_i, \phi_j) = \int_0^L a \frac{\partial \phi_i}{\partial x} \frac{\partial \phi_j}{\partial x} dx$$

$$B(\phi_i, u) = \int_0^L a \frac{\partial \phi_i}{\partial x} \left(\frac{\partial \phi_1}{\partial x} c_1 + \frac{\partial \phi_2}{\partial x} c_2 \right) dx$$

when $i=1$

$$B(\phi_1, u) = c_1 \int_0^L a \frac{\partial \phi_1}{\partial x} \frac{\partial \phi_1}{\partial x} dx + c_2 \int_0^L a \frac{\partial \phi_1}{\partial x} \frac{\partial \phi_2}{\partial x} dx \quad - \text{Eq 1}$$

when $i=2$

$$B(\phi_2, u) = c_1 \int_0^L a \frac{\partial \phi_2}{\partial x} \frac{\partial \phi_1}{\partial x} dx + c_2 \int_0^L a \frac{\partial \phi_2}{\partial x} \frac{\partial \phi_2}{\partial x} dx \quad - \text{Eq 2}$$

$$\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} =$$

So first step is that we say that $u = c_j \phi_j$, $j = 1$ to n and in this case for purposes of simplicity we limit $n = 2$. So the size of our B metrics will be $2/2$, let us calculate how that, how do we figure out what are the terms in that matrix and then w is ϕ_i , then b of $\phi_j = 0$ to L a times right, so I am right now just working on the B matrix and I have to sum it up over $j = 1$ to n so this equal to integral of 0 to L a times $d \phi_i$ over dx right, and I have to sum these things on the end is G on the end is j right. So what do I get $d \phi_1$, see ϕ_1 could be 1 and 2 it can know only 2 values right.

Because $n = 2$ so $d \phi_1$ over dx times $c_1 + d \phi_2$ over dx times c_2 dx agreed, okay so now in this equation I can vary, in one case I will be 1 and in another case I will be 2 , I can have 2 values because $n = 2$ right, okay. So when $i = 1$ what do I get, B_{ϕ_1, ϕ_j} , $\phi_j = 0$ to L so i equals one times $d \phi_1$ over dx times $c_1 + \text{integral } 0 \text{ to } L, a d \phi_1 \text{ over } dx \text{ times } d \phi_2 \text{ over } dx \text{ times } dx$ and when $i =$ then my B functional is. So here $i =$ instead of 1 now I will put 2 right and this equals 0 to L .

c_2 , c_2 where should I put c_2 and there has to be a dx also here and actually this should not be it should be u , because I have this, this entire thing is u like this entire thing is u , so this is equal to $d\phi$ and instead of if $i = 2$ then I get here this thing okay, so I am getting two equations, one is for B of $\phi 1_u$ and the other is B of $\phi 2_u$ and now I identify these things so what I do before I move this c_1 , c_1 is a constant but it is unknown so I move it here outside the integral sign I moved it outside the integral sign.

And then this term is B_{11} , this integral term is B_{12} , this integral term is B_{21} , and this integral term is B_{22} , understood so this is how I calculate the values of B 's. I know what kind of ϕ I have so I can integrate these and get the entire B matrix which is in this case $2/2$, if n was 3 then this B would have been $3/3$ and so on and so forth. So my equation is B_{11} , B_{12} , B_{21} , B_{22} , C_1 , C_2 see c_1 and c_2 are unknowns, so these equation 1 and this is equation 2 can be represented by this $2/2$ metrics multiplied by this column vector, this vector on C and on the right hand side what do I get.

(Refer Slide Time: 20:50)

EXAMPLE

$\rightarrow B(u, v) = \int_{\Omega} u v \quad \text{① } B \text{ is bilinear \& symmetric}$

$I = \frac{1}{2} B(u, u) - \int_{\Omega} f(u)$

$\delta I = 0$

Assume $u_h = \sum_{j=1}^n c_j \phi_j + \phi_0 \quad \text{②}$

ϕ_0 is in ϕ :

$B[\phi_0, (\sum_{j=1}^n c_j \phi_j + \phi_0)] = \int_{\Omega} \phi_0 \quad \text{③}$

Because B is bilinear,

$\sum_{j=1}^n B[\phi_0, \phi_j] c_j = \int_{\Omega} \phi_0 - B(\phi_0, \phi_0) \quad \text{④}$ if eqn is unknown

if

$$\begin{bmatrix} B \end{bmatrix} \begin{bmatrix} c \end{bmatrix} = \begin{bmatrix} F \end{bmatrix}$$

known
known

I get the f equation you know the terms involving the f vector I basically do the same thing on l_u the linear term, I do the same thing on l_u and I will get.

(Refer Slide Time: 21: 04)

EXAMPLE

$$B(u, v) = \int_a^b \frac{dr_u}{ds} \cdot \frac{dr_v}{ds} ds$$

$$r = \sum_{j=1}^N u_j \rho_j \quad N=2$$

$$B(r_1, r_1) = \int_a^b \frac{dr_1}{ds} \cdot \frac{dr_1}{ds} ds$$

$$B(r_1, r_1) = \int_a^b \frac{dr_1}{ds} \cdot \left(\frac{dr_1}{ds} \cdot c_1 + \frac{dr_2}{ds} \cdot c_2 \right) ds$$

where $N=1$:

$$B(r_1, r_1) = c_1 \int_a^b \frac{dr_1}{ds} \cdot \frac{dr_1}{ds} ds + c_2 \int_a^b \frac{dr_1}{ds} \cdot \frac{dr_2}{ds} ds \quad \text{--- EQ 1}$$

where $N=2$:

$$B(r_2, r_2) = c_1 \int_a^b \frac{dr_2}{ds} \cdot \frac{dr_1}{ds} ds + c_2 \int_a^b \frac{dr_2}{ds} \cdot \frac{dr_2}{ds} ds \quad \text{--- EQ 2}$$

$$\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} = f$$

My f1 and f2, any questions confusion how I get f okay, so this is how we get this B metrics and then we multiply it by this vector of unknowns which is the c column and that equals the f vector. Now the way you calculate this f vector is that you have to go back to your definition of this L_u term right, okay so that is what we will do in next 5-7 minutes okay. So and for that again we have to go back and refer to the original equation so let us go back and see the definition of L okay.

(Refer Slide Time: 21: 57)

Handwritten mathematical derivation on a whiteboard:

$$J(u) = \int_0^L \left(\frac{1}{2} a(x) u'^2 - b(x) u \right) dx - \left[\frac{1}{2} a(x) u'^2 \right]_0^L - B.C. \quad \begin{matrix} u(0) = u_0 \\ u(L) = u_L \end{matrix}$$

$$\delta J(u; v) = \int_0^L \left(a(x) u' v' - b(x) v \right) dx - \left[a(x) u' v \right]_0^L + \left[\frac{1}{2} a(x) u'^2 \right]_0^L$$

$$0 = \int_0^L \left(\frac{d}{dx} (a(x) u') + b(x) \right) v dx + \left[a(x) u' v \right]_0^L = 0$$

✓ VARIATIONAL FORM

• If diff eqn is linear and of even order, we can form a symmetric bilinear form in u, v .

So in my definition of L I have this $wa \, du$ over dx and also w times q okay, now in this case $a(x) = 0$ u_0 is I mean excuse me, at $x = L$ at $x = L$ I have specified that this is a $du/dx = 0$ so this term is 0 right, and at $x = 0$ u_0 is not specified so w will be 0 because it represents the variation and because the, that thing is specified then it is 0 so, so in my L functional which is a linear functional only this term will appear, only this term will appear in context of these boundary conditions, if the boundary conditions differ then it will it can change okay it can change.

(Refer Slide Time: 23: 08)

LINEAR - BILINEAR & QUADRATIC FUNCTIONALS

Example

$$-\frac{d}{dx} \left[a \frac{du}{dx} \right] - \frac{f}{\gamma} = 0$$

Weak form

$$\int_0^L a \frac{du}{dx} \frac{dv}{dx} dx = \int_0^L q u dx - \left[u a \frac{dv}{dx} \right]_0^L$$

Boundary conditions

Linear in u Linear in v

Bilinear & symmetric

$B(u, v)$ $f(v)$

$B(u, v) = \int_0^L a \frac{du}{dx} \frac{dv}{dx} dx$ $f(v) = \int_0^L q u dx - \left[u a \frac{dv}{dx} \right]_0^L$

Weak form

Linear in u Linear in v

Bilinear & symmetric

$B(u, v)$ $f(v)$

$B(u, v) = \int_0^L a \frac{du}{dx} \frac{dv}{dx} dx$ $f(v) = \int_0^L q u dx - \left[u a \frac{dv}{dx} \right]_0^L$

So, so what we will do is so if I move this to the right side this will become a positive thing so that is what we are going to calculate.

(Refer Slide Time: 23: 20)

The image shows a digital whiteboard with handwritten mathematical equations in red ink. The equations are as follows:

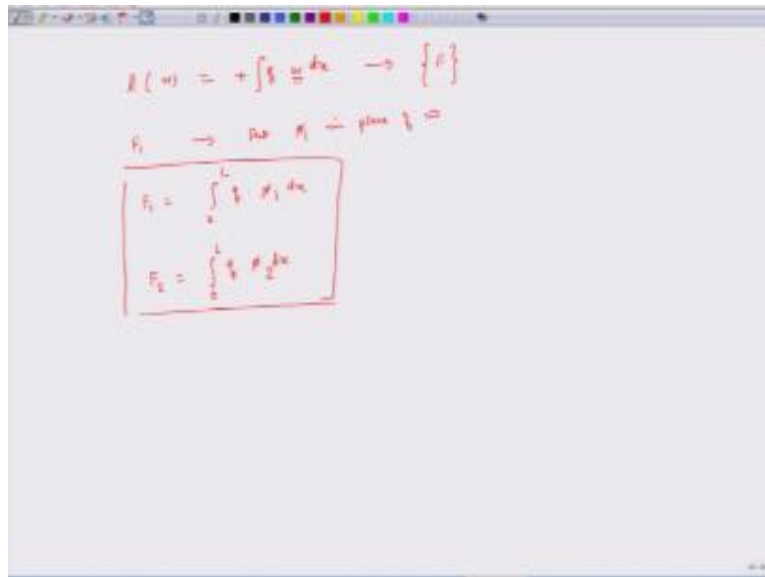

$$h(x) = + \int q \cdot dx \rightarrow \{ \rho \}$$

$$f_1 \rightarrow \rho_1 \text{ --- place } q \Rightarrow$$

$$f_1 = \int q$$

So my linear functional was what, actually it was q times w d_r right, and it has a positive sign because I moved it to the right side, now this will give me the f vector. How do I get a vector for f_1 , I put, I put ϕ_1 in place of w so I get $f_1 = \text{integral of } q$ and I know q , q can be a constant or it is a varying function I do not, it depends on the nature of the problem but that is known.

(Refer Slide Time: 24: 23)

$$f(x) = + \int_a^x f(x) dx \rightarrow \{f\}$$

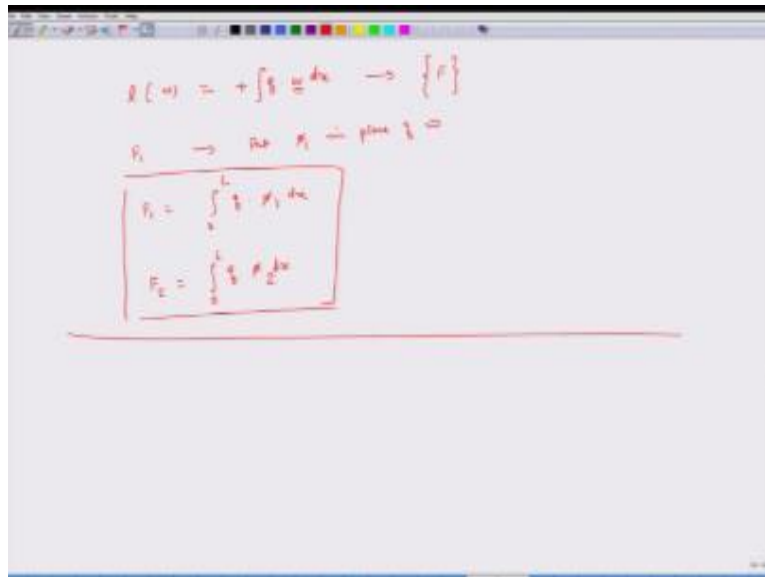

$$f_i \rightarrow \text{put } f_i \text{ in place of } f \Rightarrow$$

$$f_1 = \int_a^L f_1 dx$$

$$f_2 = \int_a^L f_2 dx$$

So this time ϕ_i times d_x 0 to L okay, and similarly f_2 in this case the choice of w is ϕ_2 so it is 0 to 1 q times, ϕ_2 times d_x so here i is 1 and here i is 2, so these are the definitions of f_1 and f_2 and what kind of ϕ_1 and ϕ_2 I have to choose which these ϕ have to meet which conditions, the essential boundary conditions they need not need meet the natural boundary conditions.

(Refer Slide Time: 25: 18)

The image shows a digital whiteboard with handwritten mathematical notes in red ink. At the top, the equation $q(x) = + \int_0^L \frac{w}{2} dx \rightarrow \{F\}$ is written. Below it, the text $P_1 \rightarrow \text{but } P_1 \rightarrow \text{plane } \frac{1}{2} \Rightarrow$ is present. A red rectangular box encloses the following two equations: $P_1 = \int_0^L \frac{1}{2} P_1 dx$ and $P_2 = \int_0^L \frac{1}{2} P_2 dx$. A horizontal red line is drawn below the box.

Now they need not meet the natural boundary conditions so that is there, so this is what I wanted to discuss in this particular example and what we will do in the next class is we will actually do one more example so here so initially we have discussed.

(Refer Slide Time: 25: 43)

EXAMPLE

$$B(u, v) = \int_0^L a \frac{du}{dx} \frac{dv}{dx} dx$$

$$B(\phi_1, u) = \int_0^L \left[\frac{d\phi_1}{dx} \frac{du}{dx} \right] dx$$

$$B(\phi_1, u) = \int_0^L a \frac{d\phi_1}{dx} \left[\frac{du}{dx} c_1 + \frac{d\phi_2}{dx} c_2 \right] dx$$

where $n=1$

$$B(\phi_1, u) = c_1 \int_0^L a \frac{d\phi_1}{dx} \frac{du}{dx} dx + c_2 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_2}{dx} dx$$

where $n=2$

$$B(\phi_2, u) = c_1 \int_0^L a \frac{d\phi_2}{dx} \frac{du}{dx} dx + c_2 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_2}{dx} dx$$

$$\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{Bmatrix} c_1 \\ c_2 \end{Bmatrix} = \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix}$$

Everything in a very abstract sense.

(Refer Slide Time: 25: 46)

EXAMPLE

$$B(u, v) = \int_0^L a \frac{du}{dx} \frac{dv}{dx} dx$$

$$u = \sum_{j=1}^J a_j \phi_j \quad N=2$$

$$v = \phi_i$$

$$B(\phi_i, u) = \int_0^L a \frac{d\phi_i}{dx} \frac{du}{dx} dx$$

$$B(\phi_i, u) = \int_0^L a \frac{d\phi_i}{dx} \left[\frac{d\phi_1}{dx} c_1 + \frac{d\phi_2}{dx} c_2 \right] dx$$

when $i=1$:

$$B(\phi_1, u) = c_1 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_1}{dx} dx + c_2 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_2}{dx} dx \quad - \text{B}_{11}, \text{B}_{12}$$

when $i=2$:

$$B(\phi_2, u) = c_1 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_1}{dx} dx + c_2 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_2}{dx} dx \quad - \text{B}_{21}, \text{B}_{22}$$

$$\rightarrow \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{Bmatrix} c_1 \\ c_2 \end{Bmatrix} = \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix}$$

Then we went ahead.

(Refer Slide Time: 25: 48)

EXAMPLE

$$B(u, u) = \int_0^L a \frac{du}{dx} \frac{du}{dx} dx$$

$$u = \sum_{j=1}^J \eta_j \phi_j \quad N=2$$

$$B(\phi_1, u) = \int_0^L a \frac{d\phi_1}{dx} \frac{du}{dx} dx$$

$$B(\phi_1, u) = \int_0^L a \frac{d\phi_1}{dx} \left[\frac{d\phi_1}{dx} c_1 + \frac{d\phi_2}{dx} c_2 \right] dx$$

where $N=2$

$$B(\phi_1, u) = c_1 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_1}{dx} dx + c_2 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_2}{dx} dx$$

where $N=2$

$$B(\phi_2, u) = c_1 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_1}{dx} dx + c_2 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_2}{dx} dx$$

$$\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{Bmatrix} c_1 \\ c_2 \end{Bmatrix} = \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix}$$

And actually this was.

(Refer Slide Time: 25: 49)

The image shows a whiteboard with handwritten notes in black ink. At the top, the title "VARIATIONAL METHODS" is underlined. Below it, the section "RAYLEIGH RITE METHOD" is also underlined and preceded by a circled number 1. The notes consist of several bullet points: the first states "We deal with weak form of the equation"; the second defines $u = \sum_{j=1}^N c_j \phi_j$ and notes that ϕ_j are linearly independent; the third states $u \approx \hat{u}$; the fourth states that c_j are called Ritz coefficients; the fifth states that they have to meet only FOC's; and the sixth states that the method works well for systems where $B(u, u) \ll B(u, v) + B(v, u)$. At the bottom left, there is a small "E:" and a horizontal line.

VARIATIONAL METHODS

① RAYLEIGH RITE METHOD

- We deal with weak form of the equation.
- $u = \sum_{j=1}^N c_j \phi_j \rightarrow \phi_j$ are linearly independent.
- $u \approx \hat{u}$
- c_j are called Ritz coefficients.
- ϕ_j they have to meet only FOC's.
- Works well for systems where $B(u, u) \ll B(u, v) + B(v, u)$.

E:

This

(Refer Slide Time: 25: 52)

EXAMPLE

$$B(u, v) = \int_0^L a \frac{du}{dx} \frac{dv}{dx} dx$$

$$u = \sum_{j=1}^N c_j \phi_j \quad N=2$$

$$v = \phi_i$$

$$B(\phi_i, u) = \int_0^L a \frac{d\phi_i}{dx} \frac{du}{dx} dx$$

$$B(\phi_i, u) = \int_0^L a \frac{d\phi_i}{dx} \left[\frac{dx}{dx} c_1 + \frac{d\phi_2}{dx} c_2 \right] dx$$

where $i=1$

$$B(\phi_1, u) = c_1 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_1}{dx} dx + c_2 \int_0^L a \frac{d\phi_1}{dx} \frac{d\phi_2}{dx} dx$$

where $i=2$

$$B(\phi_2, u) = c_1 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_1}{dx} dx + c_2 \int_0^L a \frac{d\phi_2}{dx} \frac{d\phi_2}{dx} dx$$

$$\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{Bmatrix} c_1 \\ c_2 \end{Bmatrix} = \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix}$$

Is the abstract sense where we said that we will get an set of equations b times c = f and then we actually made it more tangible and for $n = 2$ we have computed the values of B11, B12, B2 to B1, and also f1 and f2 and then the next example we will actually do a real equation and we will solve for some of these terms. Now 1, 2 important things I wanted to make.

(Refer Slide Time: 26: 25)

EXAMPLE

$$B(u, v) = \int_a^b u \frac{dv}{dx} \frac{dx}{dx}$$

$$u = \sum_{j=1}^N u_j \phi_j$$

$$v = \phi_1$$

$$B(u, v) = \int_a^b \sum_{j=1}^N u_j \phi_j \frac{d\phi_1}{dx} \frac{dx}{dx}$$

$$B(u, v) = \int_a^b u \frac{d\phi_1}{dx} \frac{dx}{dx}$$

where $N=2$

$$B(\phi_1, v) = \int_a^b \phi_1 \frac{d\phi_1}{dx} \frac{dx}{dx} + \int_a^b \phi_1 \frac{d\phi_2}{dx} \frac{dx}{dx}$$

where $N=2$

$$B(\phi_2, v) = \int_a^b \phi_2 \frac{d\phi_1}{dx} \frac{dx}{dx} + \int_a^b \phi_2 \frac{d\phi_2}{dx} \frac{dx}{dx}$$

→ $\begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} = \begin{bmatrix} F_1 \\ F_2 \end{bmatrix}$

These were. first thing is that if you look at this B metrics and if you look at these terms B12 and B21 they are same right because if u d Ø1 over dx times d Ø2 over dx and here differential of Ø2 with respective x times differential of Ø1 so it is asymmetric matrix and the symmetric comes because our original function B was what, it was symmetric, it is directly because of that reason, second thing suppose we had instead of our weak form was something like this, suppose our weak form was something like this.

Suppose it had a excuse so this is not a linear system right It is not a linear system if that would have been the case then when we would be when we would compute the values of B's and C's we would not get linear equations in C okay. Then we would not get linear equations in c because when we replace u with cj, Øj we will get squares and cross multiples of Cjs, you may get $c_1^2 + c_2^2 + c_1, c^2 + c_3^2 + c_1, c_3 + c_2, c_3$ and so and so forth okay, so these equations will not be linear.

These equations will not be linear and neither they will be symmetric, they are symmetric because B is symmetric and these equations are linear because B is bilinear okay, if they are linear equations they are very easy to solve, if they are non linear then it is a much tougher

problem so in at least in context of the discussion we will be having in this course we will be only solving linear problems okay.

(Refer Slide Time: 28: 31)

EXAMPLE

$$\vec{B}(\omega, u) = \int_a^L \alpha \frac{d\omega}{dx} \left(\frac{du}{dx} \right) dx$$

$$\vec{B}(\omega, u) = \int_a^L \sum_{j=1}^n \alpha \frac{d\omega_j}{dx} \frac{du}{dx} dx$$

$$\vec{B}(\omega, u) = \int_a^L \alpha \frac{d\omega_j}{dx} \left\{ \frac{du_1}{dx} u_1 + \frac{du_2}{dx} u_2 \right\} dx$$

where $n=2$

$$\vec{B}(\omega_1, u) = \int_a^L \alpha \frac{d\omega_1}{dx} \frac{du}{dx} dx + \int_a^L \alpha \frac{d\omega_2}{dx} \frac{du}{dx} dx \quad \text{--- EQ 1}$$

where $n=2$

$$\vec{B}(\omega_2, u) = \int_a^L \alpha \frac{d\omega_2}{dx} \frac{du}{dx} dx + \int_a^L \alpha \frac{d\omega_1}{dx} \frac{du}{dx} dx \quad \text{--- EQ 2}$$

$$\rightarrow \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix} \begin{Bmatrix} u_1 \\ u_2 \end{Bmatrix} = \begin{Bmatrix} F_1 \\ F_2 \end{Bmatrix}$$

So suppose so that is one thing.

(Refer Slide Time: 28: 34)

EXAMPLE

$\rightarrow B(u, v) = I(u)$ ① B - bilinear & symmetric

$I = \frac{1}{2} B(u, u) - \bar{L}(u)$

$\delta I = 0$

Assume $u_0 = \sum_{j=1}^N c_j \phi_j + \phi_0$ ②

Put ② in ①:

$B\left[\phi_0, \left(\sum_{j=1}^N c_j \phi_j + \phi_0\right)\right] = \bar{L}(\phi_0)$ ③

Because B is bilinear,

$\sum_{j=1}^N B[\phi_0, \phi_j] c_j = \bar{L}(\phi_0) - B(\phi_0, \phi_0)$ ④

N eqns
 N unknowns

$[B]\{c\} = \{F\}$

UNKNOWNS KNOWN

The other thing is that I also had this ϕ_0 term this ϕ_0 term, now ϕ_0 term helps us take care of so suppose you have a bar and there is a displacement 5 millimeters here then all these ϕ all the values of ϕ_j it will be 0 at this end and this end right that is how we are picking up, but then at the end there is some displacement which is 5 millimeters so that is 5 done through this introduction of ϕ_0 okay. So that takes care of the non homogeneous boundary conditions related to essential related to primary variables, related to primary variables okay, these ϕ take care of the homogeneous conditions related to primary variables.

We had discussed this earlier, homogeneous condition means things are equal to 0 if there is a non-homogeneous condition.

(Refer Slide Time: 29: 49)

EXAMPLE

$\rightarrow B(u, v) = f(u)$ ① B is symmetric

$I = \frac{1}{2} B(u, u) = f(u)$

$\delta I = 0$

Assume $u = \sum_{j=1}^n c_j \phi_j + \phi_0$ ②

Put ② in ①:

$B\left[\phi_i, \left(\sum_{j=1}^n c_j \phi_j + \phi_0\right)\right] = f(\phi_i)$ ③

Becom B is bilinear.

$\sum_{j=1}^n B[\phi_i, \phi_j] c_j = f(\phi_i) - B(\phi_i, \phi_0)$ ④

if eqns are unknown

$\begin{bmatrix} B \\ \text{Unknown} \end{bmatrix} \begin{bmatrix} c \\ \text{Unknown} \end{bmatrix} = \begin{bmatrix} f \\ \text{Unknown} \end{bmatrix}$

Then this is ϕ_0 term takes care of that so that is why we had introduced this term ϕ_0 okay, so but the mathematics is identical so we do not have to worry about it mathematics, mathematics is identical.

(Refer Slide Time: 30: 06)

EXAMPLE

$$B(w, u) = \int_a^b a \frac{dw}{dx} \left(\frac{du}{dx} \right) dx$$

$$B(p_1, u) = \int_a^b a \frac{dp_1}{dx} \frac{du}{dx} dx$$

$$B(u, u) = \int_a^b a \frac{du}{dx} \frac{du}{dx} dx$$

$$B(p_1, u) = \int_a^b a \frac{dp_1}{dx} \left[\frac{du}{dx} \cdot c_1 + \frac{dp_2}{dx} \cdot c_2 \right] dx$$

where $i=1$

$$B(p_1, u) = \int_a^b a \frac{dp_1}{dx} \frac{du}{dx} dx + c_1 \int_a^b a \frac{dp_1}{dx} \frac{dp_2}{dx} dx$$

where $i=2$

$$B(p_2, u) = c_1 \int_a^b a \frac{dp_2}{dx} \frac{du}{dx} dx + c_2 \int_a^b a \frac{dp_2}{dx} \frac{dp_2}{dx} dx$$

$$\rightarrow \begin{bmatrix} c_1 & c_2 \end{bmatrix} \begin{bmatrix} B_{11} \\ B_{12} \\ B_{21} \\ B_{22} \end{bmatrix} = \begin{bmatrix} F_1 \\ F_2 \end{bmatrix}$$

So that concludes our discussion, in the next class we will continue this discussion and do one or two very practical examples of actual differential equations so that you become more familiar with this method, thank you.
