

Basics of Finite Element Analysis – Part II
Prof. Nachiketa Tiwari
Department of Mechanical Engineering
Indian Institute of Technology, Kanpur

Lecture -15
Approximations-Part I

Hello. Welcome to Basic of Finite Element Analysis. This is the third week of this course and today is the third day. Yesterday we were developing or we have developed an expression for creating approximation functions of nth order in the natural coordinate system.

(Refer Slide Time: 00:30)

DERIVE (LAGRANGIAN) FAMILY OF INTERPOLATION FUNCTION

$\delta_{ij}(x_j) = \begin{cases} 1 & \text{if } i=j \\ 0 & \text{if } i \neq j \end{cases}$

$y_i(x_j) = \begin{cases} 1 & \text{if } i=j \\ 0 & \text{if } i \neq j \end{cases} \quad \delta_{ij}$

$n = \text{no. of nodes}$

$y_i(x) = c_i (x - x_1)(x - x_2) \dots (x - x_{i-1})(x - x_{i+1}) \dots (x - x_n)$

$y_i(x_i) = 1 = c_i (x_i - x_1)(x_i - x_2) \dots (x_i - x_{i-1})(x_i - x_{i+1}) \dots (x_i - x_n)$

$c_i = \frac{y_i(x_i)}{(x_i - x_1)(x_i - x_2) \dots (x_i - x_{i-1})(x_i - x_{i+1}) \dots (x_i - x_n)}$

$y_i(x) = \frac{(x - x_1)(x - x_2) \dots (x - x_{i-1})(x - x_{i+1}) \dots (x - x_n)}{(x_i - x_1)(x_i - x_2) \dots (x_i - x_{i-1})(x_i - x_{i+1}) \dots (x_i - x_n)}$

And this is the expression we had generated so the power of this expression is that we can generate very easily, any order approximation functions using this relation and it can be very easily computed. What we will do today in the first part is actually developed some of these approximation functions in natural coordinate system for 2 different values, so you can get little bit practice of how to use these functions in terms of how to use how to use this relation and generate approximation functions.

(Refer Slide Time: 01:19)

From (A) \times (B)

$$y_i(z) = \frac{(z - z_1)(z - z_2) \dots (z - z_{i-1})(z - z_{i+1}) \dots (z - z_n)}{(z_1 - z_1)(z_1 - z_2) \dots (z_1 - z_{i-1})(z_1 - z_{i+1}) \dots (z_1 - z_n)}$$

$n=2$: Approx. function \rightarrow linear

Diagram: z axis with nodes at -1 and $+1$. $y_1(z)$ is 1 at $z=-1$ and 0 at $z=+1$. $y_2(z)$ is 0 at $z=-1$ and 1 at $z=+1$.

$$y_1(z) = \frac{(z - z_2)}{(z_1 - z_2)} = \frac{(z - 1)}{(-1 - 1)} = -\frac{1}{2}(z - 1)$$

$$y_2(z) = \frac{(z - z_1)}{(z_2 - z_1)} = \frac{(z - (-1))}{(1 - (-1))} = \frac{1}{2}(z + 1)$$

$n=3$

$$y_1(z) = \frac{(z - z_2)(z - z_3)}{(z_1 - z_2)(z_1 - z_3)} = \frac{(z - 1)(z - 2)}{(-1 - 1)(-1 - 2)} = \frac{(z - 1)(z - 2)}{2}$$

$$y_2(z) = \frac{(z - z_1)(z - z_3)}{(z_2 - z_1)(z_2 - z_3)} = \frac{(z - (-1))(z - 2)}{(1 - (-1))(1 - 2)} = \frac{(z + 1)(z - 2)}{-2}$$

$$y_3(z) = \frac{(z - z_1)(z - z_2)}{(z_3 - z_1)(z_3 - z_2)} = \frac{(z - (-1))(z - 1)}{(2 - (-1))(2 - 1)} = \frac{(z + 1)(z - 1)}{3}$$

So, what we will do is, the first thing we will do is we will generate approximation functions when n is equal to 2. So this means that the approximate function will be linear. It will be linear in nature. So you have the zeta coordinate system and it is first node is located at minus 1 and the second node is located at plus 1 and it has only 2 nodes; node 1 and node 2. There is no intermediate node. So we have to generate ψ_1 as a function of zeta and ψ_2 as a function of zeta.

This is what we have to generate. So ψ_1 zeta equals, right so what is the value of i in this case, 1. So if it is i is equal to 1 and how many if i is equal to 1, then I will not have ψ_1 in to minus ψ_1 . Right because the value of ψ_1 is at first node is going to be 1. So I will not have ψ_1 minus ψ_1 term. So that will be there. So I will have ψ_1 minus ψ_2 ψ_1 minus ψ_2 . And will have ψ_3 , ψ_4 , and all that, I will not have, right because this index will only go up to 2. And in the denominator again I will not have ψ_1 minus ψ_1 , but I will have ψ_1 ψ_1 minus ψ_2 or zeta I am sorry zeta 1 minus zeta 2 in denominator. I will have zeta 1 minus zeta 2.

So, if I simplify, I get so denominator zeta 1 minus zeta 2 is minus 2. So that is my denominator into zeta minus zeta 2. And let us look at it is value at zeta equals minus 1, at zeta equals minus 1, what is the value of this. You please calculate it will be 1, minus 1, minus zeta 2 is plus 1 so minus 1 minus 1 is equal to minus 2 minus 2 into minus 1 is 2 2 divided by 2 is 1. So this is at it is value is at 1 zeta equals minus 1. And at zeta

equals plus 1, it is value 0. Let us look at ψ_2 , ψ_2 as a function of ζ is equal to so from equation c what is the first term will have it. $\zeta - \zeta_1$ and we will not have $\zeta - \zeta_2$. Because when ζ becomes ζ_2 then this will become 0 so we do not have that term. And then divided by $\zeta_2 - \zeta_1$, and in the denominator so the denominator is 2, and the numerator is $\zeta - \zeta_1$.

Let us look at it is value again. It is value is 0 at ζ equals minus 1. And 1 at ζ equals plus 1. We will do another example then we will move on to this was for n equals 2. Now we will do n equals 3. So if n equals 3 then we have what kind of approximation function will be will we have, it will have we will have quadratic approximation functions. The nodes will be at 1 minus 1 and 0. This is node number 1, this is node number 2 this is node number 3. And we are interested in finding out ψ_1 ψ_2 and ψ_3 .

So, let us write an expression for ψ_1 , ψ_1 as a function of ζ equals, so I have this this corresponds to the first node. So I will not have $\psi_1 - \psi_1$ term right. And I will have first term will be $\psi_1 \zeta_1 - \zeta_2$. And the second term will be $\zeta_1 - \zeta_3$. Right and in the denominator I will have sorry $\zeta - \zeta_2$. So in the numerator the first term will be $\zeta - \zeta_2$ the second term $\zeta - \zeta_3$. And in the denominator it will be $\zeta_1 - \zeta_2$ and $\zeta_1 - \zeta_3$.

So, the denominator is this, $\zeta_1 - \zeta_2$ is minus 1, and $\zeta_1 - \zeta_3$ is minus 2. Right so this is equal to 1 by 2 into $\zeta - \zeta_2$ $\zeta - \zeta_3$. And let us look at it is values. So at it is value is when ζ equals ζ_1 , what does the numerator become, 1 minus 0 into 1 minus excuse me minus 1, so what does it value become it becomes 1 by 2 into minus 1 into minus 2, in this equals 1 at ζ equals minus 1. At ζ equals 0 it becomes 1 by 2, into 0 at ζ equals 0. And this is equal to 1 by 2 into 0 at ζ equals plus 1.

The expression for ψ_2 and that equals in the numerator the first term will be $\zeta - \zeta_1$, and the second term will be $\zeta - \zeta_3$, and the denominator it will be $\zeta_2 - \zeta_1$, and $\zeta_2 - \zeta_3$. And this equals minus 1 times $\zeta - \zeta_1$ $\zeta - \zeta_3$. And the value is 0, 1, 0 this is at ζ equals minus 1 at ζ equals 0 at ζ equals plus 1, any questions?

(Refer Slide Time: 10:40)

Handwritten notes on a digital whiteboard showing the derivation of quadratic approximation functions for $n=3$.

For $n=3$, the functions are:

$$\psi_1(\xi) = \frac{(\xi - \xi_2)(\xi - \xi_3)}{(\xi_1 - \xi_2)(\xi_1 - \xi_3)} = \frac{1}{2}(\xi - \xi_2)(\xi - \xi_3)$$

$$\psi_2(\xi) = \frac{(\xi - \xi_1)(\xi - \xi_3)}{(\xi_2 - \xi_1)(\xi_2 - \xi_3)} = (-1)(\xi - \xi_1)(\xi - \xi_3)$$

$$\psi_3(\xi) = \frac{(\xi - \xi_1)(\xi - \xi_2)}{(\xi_3 - \xi_1)(\xi_3 - \xi_2)} = \frac{1}{2}(\xi - \xi_1)(\xi - \xi_2)$$

The nodal values for these functions are:

ξ	ψ_1	ψ_2	ψ_3
$\xi = -1$	1	0	0
$\xi = 0$	0	1	0
$\xi = +1$	0	0	1

APPROXIMATION OF GEOMETRY

It maps an "actual" element to an element in local natural co-ord. system.

Diagram showing the mapping from a global coordinate system (nodes 1, 2, 3 at x_A, x_B, x_C) to a local coordinate system (nodes 1, 2, 3 at $-1, 0, +1$) via the function $f(\xi)$.

In this case a linear element is mapped into a linear element in ξ co-ord. system. And

$$x = f(\xi) = x_A + \frac{h}{2}(1 + \xi)$$

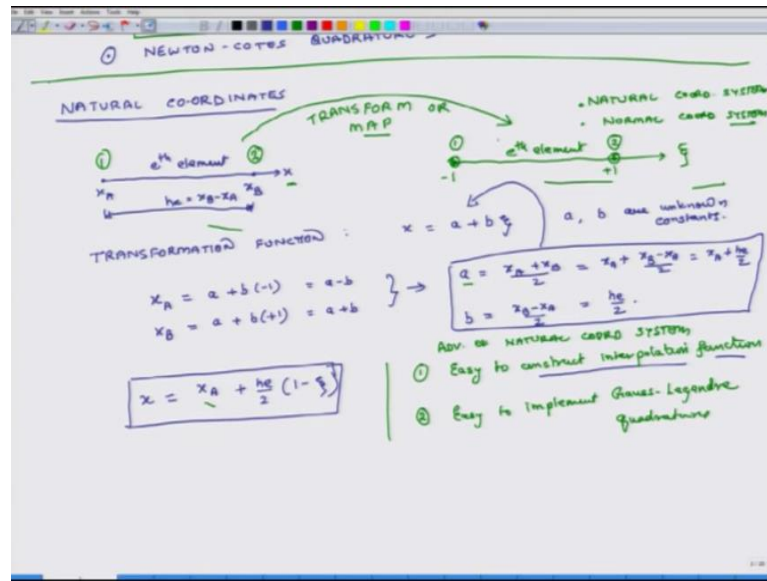

And likewise the third approximation function ψ_3 will be I will directly write this it will be half ξ minus ξ_1 , ξ minus ξ_2 . And this value is 0. 0. 1 at minus 1, at 0 at plus 1.

So, these are the expression for quadratic functions approximation functions. These are the expression for linear approximation functions. So like in a very system way and very easily we can generate approximation functions of any order legend approximation functions. I am sorry Lagrange approximation functions of any order using this equation c. So now, what we will do is we will move on to the next topic and that is all about approximation of geometry.

So what is our final goal? Our final goal is that somehow given f_x , we should be able to numerically integrated on the domain of actual element which varies from which as limits x_a to x_b . We want to integrated it, because when we have to construct stiffness matrix or k matrix k_{ij} or f_i the force vector. We have to perform this integration right. And we perform this integration over the length of an element.

Now, we have seen that if I can somehow map these elements into or on to an element in the national coordinate system. Then things become easier and more systematic. So what we have done till so far is we have developed mapping mechanism right this is what we did here.

(Refer Slide Time: 13:10)

We have developed a transformation mechanism to map the e^{th} element in actual coordinate system to e^{th} element in natural coordinate system. This is the first thing we did. The second thing is that if we are in the e^{th} element in the natural coordinate system we should be able to easily calculate the approximation functions there. We know because this is the coordinate system we are going to use, and then because our integrals will involve a lot of approximation functions, we should know how to develop those approximation functions in natural coordinate system.

So this is why we developed Lagrangian family of interpolation functions the relation for those functions in natural coordinate system, which is this relation c . So this is first part so the overall goal is to have some integrated in natural coordinate system. And for that the first requirement is that we should know how to generate Lagrangian polynomials in natural coordinate system.

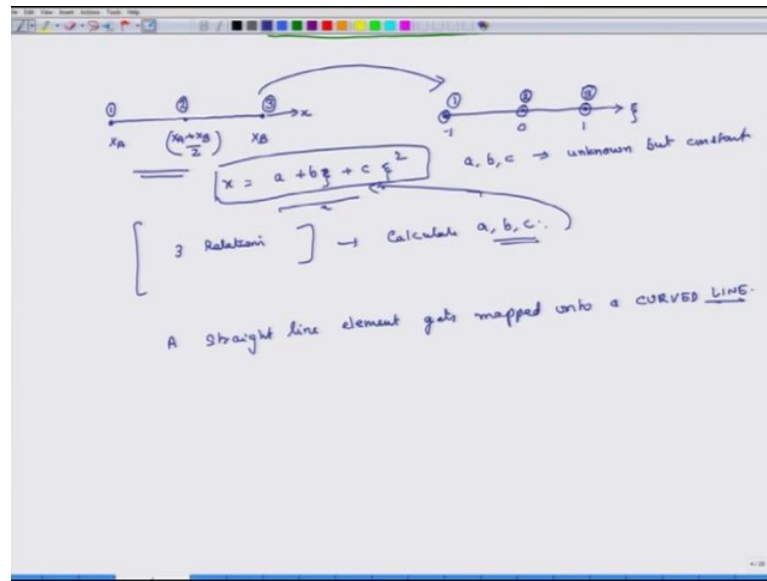

The second thing is we should know how geometry transforms. How geometry gets approximated. So this is the second piece of the puzzle. So this is the second piece of puzzle. So let us look at a function x is equal to function of ξ . Now what is this function? So this is a lower case f it is not big F when we are integrating we were saying big F that is different than this lower f small f . So what does this relation do? It maps an actual element to an element in local not local natural coordinate system. It helps us map an actual element into a local coordinate system.

For instance, if I have 2 nodes first one is located at x_a second one is located at x_b . This is node 1 this is node 2. And I have to map it to the zeta coordinate system the coordinates are minus 1 to 1. And this is zeta coordinate system right this is node 1 this is node 2. Then the transformation function is f of zeta. And in this case, in this case a linear element is mapped onto a linear element in zeta coordinate system. And $f(x)$ equals what I am sorry $f(\zeta)$, is $x_a + \frac{h}{2} \zeta$. So this is the expression we had developed earlier. This is not something new. In probably the first or second class we had developed this mapping right this is the mapping we have developed.

And what did we develop that how you transfer a 2 node element this important to understand 2 node elements to a 3 noded element in the zeta coordinate system. Is there was a 3 noded element then this mapping relation would be different. This is important to understand right because then there would be 3 constants $a + b\zeta + c\zeta^2$ and then we will have to do 3 equations and we will have to calculate a , b and c .

So, this mapping will be different it is important to understand. So that is why it is written in this case a linear element in x domain or x coordinate system is mapped on to a linear element in zeta coordinate system, and for this kind of transformation where we have 2 elements here 2 nodes here 2 nodes on the other side linear element on both sides. This is the transformation function it is important to understand. The other thing is here it is a straight line element and here also it is straight line element, so a straight line element is being mapped onto a straight line element.

(Refer Slide Time: 18:53)

Now, consider this. Suppose I do not do this and I have a different type of element right. So this is node 1 this is node 2 this is node 3. And now I am trying to map it in the zeta coordinate system. So this is my x coordinate, and here the nodes are located at minus 1 0 and 1, this is node 1, node 2, node 3. So then what is happening is, so I can say that x is equal to a plus b zeta plus c zeta square.

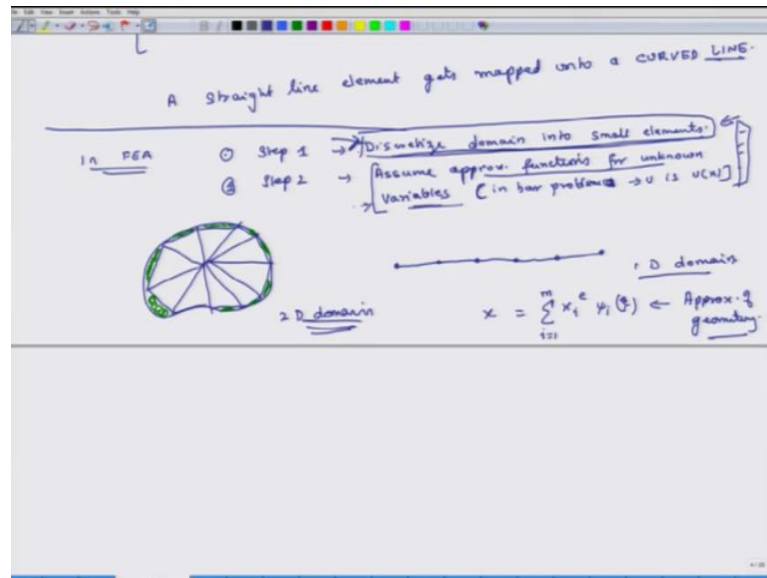

So a b and c are unknown, but constant. And how do I calculate these a b and c. Again I see that node 1 has to map to 1 and so on and so forth. So I get 3 relations, between x a, x a plus, I essentially I get 3 relations. And from these 3 relations I calculate a b and c. And then I plug this a b and c back in this equation. I plug all these values of a b c back in this equation right. And that is how I develop the domain the mapping.

Now, when I do this kind of a transformation, then what is happening? See what is happening is that here you have a straight line, so a straight line element gets mapped onto a curved line gets mapped onto a curved line. Or you can do back and forth. Because x is a straight and zeta is $1 + b x + c x$ zeta square right. So it is like a quadratic. So if you plot that x versus zeta, it would not be a straight line. Right the plot of this thing if I plot this equation, it is a linear transformation it is a straight line right. If on x axis if I plot x and y axis I will plot zeta I will get a straight line.

Here if I make the same plot this is a non-linear transformation, it is a curved line I will get curved line right. So using this kind of approaches I can also approximate curved

geometries this important to understand. We will not do more about this, but just wanted to introduce this idea so this is there.

(Refer Slide Time: 22:32)

Now, the other thing is, so this is important to understand and remember now the other important thing to notice in FEA when we wanted do a finite element analysis what we will do. The first step we do is that we break the domain into small elements right. In FEA step 1 we had discussed this in our first week, the step 1 is discretize domain into small elements. And then the second step is we assume approximation functions or interpolation functions and this are assuming for what for unknown variables.

For instance, in a bar problem, we assume that u is unknown right in bar problem u is unknown, and we assume that this unknown variable how it changes how it varies over the length of each element right. This is what we assume and when we discretize this domain into small elements. So we do other 2 things to construct assembly element equations, assembly equations, impose the boundary condition and solve the equation all that we do, but these are the first 2 things.

These are the first 2 things, but when we are doing this we are first thing is we are discretizing the domain into small elements, and the second thing is we are for unknown we are so this is an approximation right this is an approximation. Why is it an approximation? If I have this kind of a domain, I can break it up into triangles, right each of these triangles could be an element. When I discretize a mesh right when I discretize a

geometry each of these triangles could be an element. And this is the extra stuff which in this mesh I could not capture. This is a extra stuff, so when we discretize, now this problem does not happen, if I have a straight line if this is a domain, 1 d domain, this is 1 d domain this is 2 d domain, right so in 1 d domain if I break this up into smaller elements, this is the problem right.

The finite element discretization of the domain is exact. There is no error introduced because of discretization, but here when I am breaking up into small triangle or rectangles in 2 d domains I may have these green areas which are not captured in the actual thing right.

So, in finite element analysis, we not only developed approximation function for unknown variables, but we also develop approximation functions for geometry we also developed approximation functions for geometry. Right so you get introduction of a error here and also approximation functions when we develop for geometry. You get introduction of error here also right this is what we earlier also so approximation of geometry at least in 1 d domain, how does it look like that x is equal to, $x_i = \psi_i(\xi)$ ξ is equal to 1 to m . This is approximation of geometry.

Now, in straight line it will not create a problem, but in triangles and things like that this approximation geometry creates some generate errors. So this is approximation of geometry. So what we will do is we will continue this discussion about approximation geometry in the next class also. And then we will start introducing things like Jacobean and stuff like that Jacobean. Jacobean transformation and related things, because all this concept will eventually help us perform the ultimate goal is which is to do numerical integration using Gauss, Legendre scheme or Gauss Legendre quadrature method that is what our goal is so.

Thanks, and we will meet tomorrow.
