

Principles of Vibration Control
Prof. Bishakh Bhattacharya
Department of Mechanical Engineering
Indian Institute of Technology-Kanpur

Lecture-19
Controllability and Observability of System

Welcome to the course on principles of vibration control. We have reached the fag ends of our journey on vibration control in this course. Now in the remaining lectures I want to focus about the active vibration control.

(Refer Slide Time: 00:33)

Controller Canonical Form

- State space representation is not unique in nature.
- Some of the commonly used forms are mentioned here

$$\frac{d^n y}{dt^n} + \alpha_1 \frac{d^{n-1} y}{dt^{n-1}} + \dots + \alpha_n y = \beta_0 \frac{d^n u}{dt^n} + \beta_1 \frac{d^{n-1} u}{dt^{n-1}} + \dots + \beta_n u$$

→ control effort
n/n order SDE. 3-4
↓ let order again

$$A = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & 1 \\ -\alpha_n & -\alpha_{n-1} & -\alpha_{n-2} & \dots & -\alpha_1 \end{bmatrix}$$

$$C = [\beta_n - \alpha_n \beta_0 \quad 0 \quad 0 \quad \dots \quad \beta_1 - \alpha_1 \beta_0]$$

$$B = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}$$

$$D = \beta_0$$

$\dot{X} = AX + Bu$
 $Y = CX + Du$

Smart Materials Structures and Systems Laboratory IIT Kanpur

So towards that direction we are walking on states space control and for state space control we have to first of all we have talked about that how to develop the state space model but today we want to talk about certain canonical forms which will allow us to develop in the modern control that means full state feedback control for vibration control itself.

Now the first thing we have to keep in our mind and I will actually proof you that after a few more slides that state space representation state space representation is not unique in nature. Remember I told you that depending on the choice of the states the state space matrix will change. But that does not mean that the (()) (01:20) equation will change and the dynamics will change.

We will prove it because one of the most important till criteria towards that is the Eigen values of the system will not change. So no matter whatever will be your choice of state

factors we have to finally cross check that. Now since let us first of all assume that this state space representation is not unique in nature. So we are looking for certain forms which we are calling to the canonical forms. canonical in good old days has to have a relationship with cannon itself anything which will be said by charge with a cannon sound would be considered to be the last word in that direction.

But as far as our things are concerned this are certain very uniform forms that is used all over the world and hence this canonical form term came and this we will learn corresponding to 3 cases one is for controller, another is for observer and the other one is called Jordon canonical form. There were few more but these 3 are generally most useful. So we will first talk about the controller canonical form.

Now if we consider the wording equation of the system in a big generalized manner, you can see that this is the Jordon equation of the system where d is a order ordinary differential equation and this is Y is the dependent variable and time is the independent variable. So left hand side gives us that up to $\frac{d^n y}{dt^n}$ in it order and right hand side we have this u which is the control effort.

So right hand side also u get up to in its order or you know up to that kind of a I mean you need not go up to n here, you can go up to something like \bar{n} or there was something like that were n and \bar{n} need not be the same. So that is what is you know is our Jordon equation of the system where left hand side talks about the states, right hand side talks about the control effort.

Now this see this is having an n th order let say ODE of in terms of y so as a function of t . So this equation can be actually decomposed into n fast order equations. N fast order equation and that n fast order equation is going to give us the state space format of it. Now in that state space format the controller canonical form should be search that all these coefficients are only coming at the last row of the A matrix.

So in the A matrix it will start with a representation of $01, 000$, so if you look at it that this is your diagonal actually and then the super diagonal terms are all unity. So you can see that these are the super diagonal terms which are all unity, that is the way it is arranged and all

other terms are 0 here and below also all other terms are 0 except the last row. So this block is 0 and this block is 0.

And in the last row we are getting this coefficient back from the characteristic equation which is $-\alpha_n$ then $-\alpha_{n-1}$ like that it will go up to $-\alpha_1$ calling as the last term of this. That is the way if we can represent that a matrix and then the b matrix that is the actuate or influence part to remember again that we are talking about the form $\dot{x} = AX + Bu$.

So this B matrix all the entries will remain 0 except the last which will be unity that is what will be our B matrix and i earlier told you that we can develop an output matrix which is $y = CX$ sometimes it is extended up to $y = CX + Du$, if the control effort directly affects some of the outputs. So in this case control canonical form, the C matrix will have this following form ok taking coefficients from the 2 sides and D matrix is simply β_0 .

So this is what if we develop you know these nth order OD by decomposing it fast in a nth fast order and fast order equation and then writing it in this abcd form, then we are going to get the controller canonical form of the system. So this form will be useful for that is why we have to always keep this form in our mind.

(Refer Slide Time: 06:40)

Observer Canonical Form

$$\frac{d^n y}{dt^n} + \alpha_1 \frac{d^{n-1} y}{dt^{n-1}} + \dots + \alpha_n y = \beta_0 \frac{d^n u}{dt^n} + \beta_1 \frac{d^{n-1} u}{dt^{n-1}} + \dots + \beta_{n-1} u + \beta_n u$$

$$A = \begin{bmatrix} -\alpha_1 & 1 & 0 & 0 & 0 \\ -\alpha_2 & 0 & 1 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -\alpha_{n-1} & 0 & 0 & 0 & 1 \\ -\alpha_n & 0 & 0 & 0 & 0 \end{bmatrix} \quad B = \begin{bmatrix} \beta_1 - \alpha_1 \beta_0 \\ \beta_2 - \alpha_2 \beta_0 \\ \vdots \\ \beta_{n-1} - \alpha_{n-1} \beta_0 \\ \beta_n - \alpha_n \beta_0 \end{bmatrix}$$

$$C = [1 \quad 0 \quad 0 \quad \dots \quad 0] \quad D = \beta_0$$

$y = CX + Du$
 ↑ ↑ ↑
 output Sensing Disturbance
 Influence Matrix
Dual of Controller Canonical Form

 Smart Material Structures and Systems
 Laboratory
 IIT Bombay

There is another which is known as the observer canonical form. So this is just the dual of the controller canonical form. And that you can see that why this is the dual part of it you can easily see each if you look at the you know structure of the A matrix here instead of the you

know last row now it is the fast column where all these coefficients are appearing starting from $-\alpha_1$ to $-\alpha_n$.

And then if you can see that once again the super diagonal terms are unity here and no other terms are coming into picture. B matrix is not 001 now, B matrix has all these based on the coefficients drawn from this given equation. C matrix is 1000 that is why that C matrix is suppose to be corresponding to the output equation y equals to $CX + Du$ where Y is the output and that is why this is we put more focus on this that this is related to what you call the you know the sensing, ok so this is the sensing.

Like B is the actuation, this is the sensing ok, influence matrix or of course D is disturbance. So here that sensing part because observer are related to sensor wherever we cannot actually have sensors to sense the particular state we try to estimate that state and then this observer canonical form becomes useful because we have to design, we can design observer for this estimated state.

So that is why this part is simplified here as C is 1 and rest is 0 and D equals to β_0 . So this is known as the observer canonical form.

(Refer Slide Time: 09:05)

Jordan Canonical Form
(for non-repeated Eigen values)

$$\frac{d^n y}{dt^n} + \alpha_1 \frac{d^{n-1} y}{dt^{n-1}} + \dots + \alpha_n y = \beta_0 \frac{d^n u}{dt^n} + \beta_1 \frac{d^{n-1} u}{dt^{n-1}} + \dots + \beta_{n-1} u + \beta_n u$$

$$Y(s) = \left[\beta_0 + \frac{P_1}{(s - \lambda_1)} + \dots + \frac{P_n}{(s - \lambda_n)} \right] U(s)$$

$\lambda_1 \dots \lambda_n$ roots of $s^n + \alpha_1 s^{n-1} + \dots + \alpha_n = 0$

$$A = \begin{bmatrix} \lambda_1 & 0 & 0 & 0 & 0 \\ 0 & \lambda_2 & 0 & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \lambda_{n-1} & 0 \\ 0 & 0 & \dots & 0 & \lambda_n \end{bmatrix} \quad B = \begin{bmatrix} 1 \\ 1 \\ \dots \\ 1 \\ 1 \end{bmatrix}$$

$$C = [P_1 \quad P_2 \quad \dots \quad P_n] \quad D = \beta_0$$

Robot Manipulator Structure and Dynamics
Laboratory
IIT Kanpur

There is one more form that comes out this is known as Jordon canonical form and this is the form which is for non repeated Eigen values. So once again we have the same equation front of us and you can actually carry out this time of the entire equation, so Y will be Y_s , U will

be U s and you can write each one of them through a partial fraction. So these are the partial fractions, so that you actually separate it out in terms of λ n distinct roots ok.

So that is what then becomes our characteristic equation. So now if I line up all these Eigen values which are the distinct roots along the diagonal rest is all 0. Then that is what is by A matrix in the Jordan canonical form. B matrix is all unity and C matrix has all the residue corresponding to each one of these roots $(())$ (10:07) and D is β_0 . SO this is the Jordan canonical form.

So these 3 canonical forms are important for controller design that is why we have first introduced these 3 forms to you. Now this form to form this is only about it is like you know the same person who will you are putting into different dresses. All dresses corresponding to your convenience, but the person reverse the same, how do I prove that.

(Refer Slide Time: 10:39)

The slide shows the following derivation:

Invariance of Eigen values

Use $x = Tz$ (Transformation Matrix)

$$\dot{x} = Ax + Bu$$

$$\frac{d}{dt}(Tz) = ATz + Bu$$

$$\dot{z} = T^{-1}ATz + T^{-1}Bu$$

$$\dot{z} = \tilde{A}z + \tilde{B}u$$

where $\tilde{A} = T^{-1}AT$, $\tilde{B} = T^{-1}B$, and $T^{-1}T = I$.

The determinant calculation is shown as:

$$|\lambda I - T^{-1}AT| = |\lambda(T^{-1}T) - T^{-1}AT|$$

$$= |T^{-1}(\lambda I - A)T|$$

$$= |T^{-1}| |\lambda I - A| |T|$$

$$= |\lambda I - A|$$

Since $|ABC| = |A| |B| |C|$, the eigenvalues are invariant.

That you can prove from the proof of variance of the Eigen values. So if you look at it that our initial equation is given equation was \dot{X} equals to $Ax + Bu$. Now let us say that I do not want it in these form, I want it in control canonical form or observer canonical form or the other form. So let us say corresponding to that form the state vectors are not X but Z . Now first of all we are working the linear domain.

So let us assume that this X to Z a mapping is possible through this transformation matrix D . So T is our transformation matrix. So then this entire form will look like T so I am not writing X equals to Tz so this will become Tz dot that start that Ax will become ATz and Bu will

remain as it is. That is what is my second stage. In the third stage what I will do is that I will take these T out here by pre-multiplying everything both the sides by T inverse.

So if I do that then $T^{-1}T$ will be identity, so \dot{Z} will be $T^{-1}ATz + T^{-1}Bu$. Here I have paid an implicit assumption. What is that implicit assumption, that is T^{-1} exists, only they are actually these transformations would make sense. So and later on we will see that this is actually related to the controllability or observability of a system. So our new equation is a new state space equation we have obtained that is not in the form of $\dot{X} = Ax + Bu$.

But \dot{Z} equals to $T^{-1}ATz + T^{-1}Bu$. You may write that \dot{Z} equals to something like $\tilde{A}Z$ where \tilde{A} is $T^{-1}AT + T^{-1}$ where \tilde{A} is actually our $T^{-1}AT$, this is our new state matrix. And \tilde{B} is actually $T^{-1}B$. Now if this with the case then what is the Eigen value of these \tilde{A} , till that I can always find out if I can find out $\lambda I - \tilde{A}$.

So what is the determinant $\lambda I - \tilde{A}$. \tilde{A} is nothing what $T^{-1}AT$, so $\lambda I - T^{-1}AT$. That is what we get. Now let us say this I is the identity matrix and write it as $T^{-1}T$ because $T^{-1}T$ and you know the inverse of T if it exists, so $T^{-1}T$ will be identity because $T^{-1}T$ will be identity. So identity I can replace by these - $T^{-1}AT$.

And then I can take this T^{-1} you know common from both the sides, T^{-1} it will become then $\lambda I - A$ times T . So this identity matrix we are keeping here, just because this T I am taking to the right hand side. So now there are 3 matrix for us, T^{-1} , $\lambda I - A$ and T . So the determinant is the product of these 3 matrixes. Now there is a rule of determinant which says that if you have a determinant of product of 3 matrixes ABC .

Then this will be equivalent to the determinant of A times determinant of B times determinant of C . This is what we have uses here. That this will be then determinant of T^{-1} , determinant of $\lambda I - A$ and determinant of T . So If I do that then of course the determinants can be actually taken anywhere matrix cannot be, so I can take the determinant of T here and then this $T^{-1}T$ would become identity, so that all that will be left is determinant of $\lambda I - A$.

Now you can see that I started with $\lambda I - A$ that was giving me the characteristic equation and I got $\lambda I - A$ determinant, this is giving me the same characteristic equation, so what it means is that the transformation matrix has only changes the form, it has not change the Eigen values of the system. So the Eigen values are actually invariant in this case. That is the very important conclusion that help us that from fall to fall very smoothly we can jump provided this transformation matrix exists. That is the only precondition that we have to keep with us.

(Refer Slide Time: 15:52)

How to check system stability?

In state space form, the **stability** of a system depends on the **Eigen values of A** which may be obtained from the characteristic equation as follows.

If the **real parts of the roots** of this equation are strictly **negative**, then the system is considered to be asymptotically **stable**.

$$|\lambda I - A| = 0$$

e.g.

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{bmatrix}$$

$$|\lambda I - A| = \begin{vmatrix} \lambda & -1 & 0 \\ 0 & \lambda & -1 \\ 6 & 11 & \lambda + 6 \end{vmatrix}$$

$$= \lambda^3 + 6\lambda^2 + 11\lambda + 6$$

$$\lambda = -1, -2, -3 : \text{Stable System}$$

Handwritten notes:

- S-plane* (Imaginary axis vs Real axis)
- no poles* (in the right half plane)
- B=?*
- $$\lambda I = \begin{bmatrix} \lambda & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \lambda \end{bmatrix} - \begin{bmatrix} A \end{bmatrix}$$

Smart Materials Structures and Systems Laboratory IIT Kanpur

No with that we need to see a few things. For example how do we check the stability of a system. Well in state space form the stability of a system will always depend on the Eigen values of A which may be obtained from the characteristic equation. If you remember that when we are talking about these transfer function best approach then the roots I was always telling that the real parts of the roots should not go, should not become positive.

It should not go to the right hand side, that means if I plot the S plane if you remember a real part of S verses the imaginary part of S. I said that no poles can be placed in the right hand side, no poles because then it will be unstable. Now in this state space form this pole is to be replaced by the Eigen values, otherwise it remains the same. That means the real parts of the roots are Eigen values are strictly negative.

Then the system will be considered to be asymptotically stable. Let us consider you know a kind of system like say this A, this is a system if you look at it that this system looks like as it

in the control canonical form, but we cannot guarantee because we have not seen the B yet. Only when we see the B also then only we can say yes it is in control canonical form.

Now anyway our job here is to find out what are the roots, what are the Eigen values of this system where we can find out what is the determinant of this system, that is $\lambda I - A$, keep in mind that λI actually means I is a identity matrix, so $\lambda I = \begin{bmatrix} \lambda & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \lambda \end{bmatrix}$. So I can put that as $\lambda I - A$ whatever is my A matrix. If I do that you know thing I am getting this $\lambda I - A$.

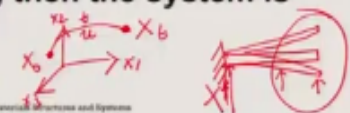

And if I do find out the determinant I am going to get this polynomial, which is a cubic polynomial of λ . Now by using that level by using other formulations you can actually (()) (18:13) options you can find out what is λ and you will see that this are the 3 roots of λ and in that means that this the stable system because the λ s are all in the left half plane. So -1, -2 and -3. So that means this is going to be a stable system.

So that is the way we can first of all check the stability of a system. Next what we can check is actually what is this are called you know the control canonical form of the system.

(Refer Slide Time: 18:50)

Controllability of a System

- A state x_1 of a system is “controllable” if all initial conditions x_0 at any previous time t can be transferred to x_1 in a finite time by some control function $u(t, x_0)$.
- If all the states are controllable then the system is completely controllable
- If controllability is restricted to depend upon t_0 , then the system is controllable at time t_0 .
- If a particular output can be obtained from any arbitrary x_0 at t_0 , then the system is output controllable.

Research Materials, Structures and Systems Laboratory IIT Kanpur

(Refer Slide Time: 18:55)

Next we want to talk about the controllability and observability of the system. Because particularly we will talk about the controllability and also in observability will check as a side by side with respect to the observer canonical form. Now let us look in to this forms. So how do you define the controllability of a system. The controllability the term itself is telling us that if we have a system were I have some actuator through which I am trying to control the vibration.

The vibration should be this actuator should be placed in such a manner that it can control the vibration. For example that we has give something like a physical significance of what we are talking about, suppose this is a cantilever beam and this beam is vibrating. Now if you want to you know control this vibration of the cantilever beam you have to place actuators. So if you place an actuator here you will be able to control.

If you place it somewhere here the effort will be increasing what still you will be able to control. If you place it very close to the structure you may be need much more force and finally if you were here on the (()) (20:16) point here itself it will be impossible for you to control. So what it means is that based on my position of actuator the controllability of the vibration mode will be actually you know determine that whether it is controllable or not.

Now for you know a particular state x_1 of a system will call it controllable when if all initial conditions X_0 at any previous time t , t can be 0 or any previous time can be transfer to a future x_1 in a finite time by some control function u_{tx0} . And this also has to be a finite control effort. So that means suppose we are in a 3 dimensional thing let us say so I have you

know a position here and this is what let say my x_0 position with respect to 3 steps suppose ok.

x_1 and x_2 and x_3 . Now from here I am going to some location here in this states space which is some x_t . If I can go from these state to this state within a finite time t and with a finite control effort u then only we will say that the systems controllable and this is simply not possible in this case that I have discuss that within a finite time if you place your actuator here you will not be able to control the vibration of the system.

So if all these states like that are controllable then the system is completely controllable. If controllability is restricted to depend up on t_0 then it is called controllable at time t_0 that is within this time it is controllable and if it is less it is not if it is more, it will be. If a particular output can be obtain from any arbitrary x_0 at t_0 then the system is called output controllable. So these are some of the subdivisions of controllability of a system. So that is the definition of controllability.

(Refer Slide Time: 22:33)

How to test the Controllability of a system?

- A system is state controllable at $t=t_0$ if there exists a continuous input $u(t)$ such that it will drive the initial states $x(t_0)$ to any final state $x(t_f)$ within a finite time interval $(t_f - t_0)$
- The Controllability matrix for a system (A, B) is defined as: $\dot{x} = Ax + Bu$

$$C = [B \quad AB \quad A^2B \quad \dots \quad A^{n-1}B]$$
- The state matrix A is of size $n \times n$.
- The system is fully controllable iff $\text{Rank}(C) = n$
if and only if

Smart Materials Structure and Systems Laboratory IIT Bombay

How do I test the controllability of a system and that is simple if you have a controllability matrix called C and then you can if you have these you know A and B from these states space representation \dot{x} equals to $Ax + Bu$. You can develop your controllability you know matrix from this C with the help of these particular formation of the matrix which is $B \quad AB \quad A^2B \quad \dots \quad A^{n-1}B$ where A is of size $n \times n$ and the system is fully controllable if and only if the rank of C equals to a number of the states.

We will then say yes the system is full state controllable from t equals to T_0 to any time t such that you will get a continuous input u and it will be able to drive it from X_{t0} to X_{ta} within a finite time interval and with a finite energy. So by checking these particular condition if this is satisfied we can say yes it is controllable. For designing before designing any controller in state space control is controllability must be checked always.

So that is the first condition. If you get it checked then the transformation the inverse of the transformation will actually exist.

(Refer Slide Time: 24:04)

The concept of Stabilizability

- In general, controllability is considered to be a very strong constraint for a multi-degrees of freedom system.
- Hence, in practice, there exists a weaker definition of controllability – this is known as stabilizability.
- Let us consider the following system which is represented in modal or block diagram form:

$$\dot{x} = \begin{bmatrix} 3 & 0 \\ 0 & -2 \end{bmatrix} x + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u$$

- This system has two roots one at 3 and hence unstable, the other at -2 and hence stable. However, the control effort exists only for the unstable mode at 3 and hence the system is partly controllable or stabilizable.

 Smart Materials Structures and Systems Laboratory
IIT Kharagpur

In some cases controllability is considered to be a very strong constraint for a multi degrees of freedom system. SO there is a weaker definition of controllability. We call it as stabilizability. For example if you look at this particular system \dot{X} equals to $AX + Bu$ where A is like this $\begin{bmatrix} 3 & 0 \\ 0 & -2 \end{bmatrix}$ and B is $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$. The system has 2 roots clearly it is only block diagonals one at 3 and another at -2. This root is unstable.

However, this root is stable. So the controller if the control effort exists only for the unstable mode at 3 and hence the system is partly controllable or stabilizable. So this is the you know partial controllability or stabilizability as a special subset.

(Refer Slide Time: 25:01)

Observability of a System

A state $x_1(t)$ at some given time is 'observable' if knowledge of the input $u(t)$ and output $y(t)$ over a finite segment of time completely determines $x_1(t)$.

A, B
Controllability

The Observability matrix for a system (A,C) is defined as:

$$O^T = [C \ C A \ \dots \ C A^{n-1}]$$

The state matrix A is of size $n \times n$.

The system is fully Observable iff $\text{Rank}(O) = n$

if and only if

Now I told you that observer canonical form gives us that is the dual problem of it that is from the same thing prospective. That a particular state $x_1(t)$ at some given time is observable, if the knowledge of $u(t)$ and output $y(t)$ over a finite segment of time can completely determines the states $x_1(t)$. So this needs this for controllability we needed the A, B for controllability if you remember.

And for you know observability we need the power of A C, we need the AC for the observability and this is define as O^T equals to this particular thing you know C CA up to CA^{n-1} . This state matrix is considered of size n by n and the system is fully controllable if and only if the rank of O equals to n . The only this is same, is fully observable. So this are the controllability and observability are 2 dual forms.

(Refer Slide Time: 26:18)

Example:

Check whether the following system is controllable and observable

$$\begin{cases} \dot{x}_1 \\ \dot{x}_2 \end{cases} = \begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} \begin{cases} x_1 \\ x_2 \end{cases} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u$$

$$y = \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{cases} x_1 \\ x_2 \end{cases}$$

Now let us say I give you a very simple example that we have this \dot{X} equals to $Ax + Bu$ and this is the A matrix to y this is B and this is C . Ok from by looking at it we can say that it is you know which may be the control canonical form because these we have the coefficients here and only at the last row and here the super diagonals unity, rest terms are into there. So any way we can first find out that what is the controllability and then we can find out what is the observability. So this is A , this is B , and this is C . So we can find it out.

(Refer Slide Time: 27:00)

Example:
Check whether the following system is controllable and observable

$$\begin{Bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{Bmatrix} = \begin{bmatrix} 1 & 1 \\ -2 & -1 \end{bmatrix} \begin{Bmatrix} x_1 \\ x_2 \end{Bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u$$

$$y = \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{Bmatrix} x_1 \\ x_2 \end{Bmatrix}$$

Solution

- The order of the Plant is 2 here. Let us obtain the Controllability and the Observability Matrices
- Following earlier definitions:

$$C = \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$$

$$B = \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$$
- Since both C and O are of rank 2 which equals to the order of the system – hence, this system is fully controllable and observable.

2×2
 $A^{n-1}B$
 $A^{2-1}B = AB$

So this controllability is what it is B and then AB , so for us what is BB is 0, 1 and what is A , B , A times B that means first row first column, that will give you that 1 into 0 + 1 into 1 so that is 1 and then second row this column so $-2 \times 0 + -1$ into 1 that will be $1 - 1 \times 1$, so that is my AB , ok we do not have to consider the additional terms because A is of 2 by 2 size so A^{n-1} , B means actually $A^{2-1}B$.

And that means AB . So we have to go only up to B AB and we get the controllability matrix, let us call it as C with a special pattern in it. So that we do not confuse it with this, so this is C . And similarly I can find out observability again the special pattern and observability is C , CAC and -1 . So we get the observability matrix point.

Now if you check that for both C and O the rank is 2 which equals to the order of the system. Hence the system is both fully controllable and observable. That is just an example to actually keep tu with construability and observability. Thank you. In the next lecture we will talk about how to apply all these concepts together for full state feedback control.
