Lecture – 59
Acoustic Enclosures

Hello again, today is the fifth day of this week and we will complete our discussion on noise from an adjacent room. And yesterday we were doing an example in which there was a large room, which was separated into two zones. The first room which was relatively larger; has a machine and the noise from that machine is coming to the adjacent room, the operator room and these two rooms are separated by a partition.

(Refer Slide Time: 00:50)

EXAMPLE

Diagram showing a Machine Room (1) and an Operator Room (2) separated by a partition. The Machine Room has a machine (M) and a window area (A). The Operator Room has a window area (A) and a partition area (A_w). The distance between the machine and the partition is d. The distance between the partition and the operator is d₂. The area of the partition is A_w. The area of the window in the operator room is A_w. The area of the window in the machine room is A.

Machine Room (1):
 $S_1 = 900 \text{ m}^2$
 $\bar{\alpha}_1 = 0.05$
 $K_1 = 4 \text{ m}$

Operator Room (2):
 $S_2 = 100 \text{ m}^2$
 $\bar{\alpha}_2 = 0.35$
 $K_2 = 1.5 \text{ m}$
 $TL = 30 \text{ dB}$

Power (Acoustic) = 0.033 W . $\alpha = 2$

QUESTION: CALCULATE L_{p2} and L_{p1} .

Answer: $L_{p2} = 105 \text{ dB}$

So, this is the problem definition; which we had described earlier and to compute the values of sound pressure level in room 2 and room 1, we had to compute three important parameters; L_w , r_1 and r_2 which are the room constants.

(Refer Slide Time: 01:07)

The image shows a whiteboard with handwritten mathematical derivations. The calculations are as follows:

$$L_w = 10 \log_{10} \left[\frac{0.033}{10^{-12}} \right] = 105 \text{ dB.}$$

$$R_1 = \frac{S_0 \left[\bar{\alpha}_1 + \frac{4 \text{ m} / s_0}{1 - \bar{\alpha}_1} \right]}{1 - \bar{\alpha}_1} = \frac{900 \times 0.05}{1 - 0.05} = 47.37 \text{ m}^2.$$

$$R_2 = \frac{S_2 \alpha_2}{1 - \alpha_2} = \frac{100 \times 0.35}{1 - 0.35} = 53.85.$$

$$L_{p_1} = L_w + 10 \log_{10} \left[\frac{Q}{R_1} + \frac{Q}{4\pi r_1^2} \right] + 0.1$$

$$= 105 + 10 \log_{10} \left[\frac{4}{47.37} + \frac{2}{4\pi \times 16} \right] + 0.1$$

$$= 94.8 \text{ dB.}$$

Additional values listed on the right side of the whiteboard:

$$Q = 2$$

$$R_1 = 47.37 \text{ m}^2$$

$$r_1 = 4 \text{ m}$$

And now that we have done those calculations, we will continue our discussion and will compute the sound pressure level in the two rooms. So, L_{p1} equals L_w ; plus $10 \log_{10}$; 4 over R_1 ; plus Q divided by $4 \pi R_1$ square plus 0.1 .

So, here Q_1 ; Q is specified as 2 , directivity factor. It is given as 2 ; we also have computed the value of R_1 ; that is the room constant. So, R_1 equals 47.37 square meters and little R_1 is 4 meters. So, with this I compute; so L_w is 105 decibels plus $10 \log_{10}$; 4 by R_1 , plus directivity factor divided by 4π into 16 ; plus 0.1 ; and this comes to be 94.8 decibels.

So, what does that mean? That in the first room; in the machine room; if I am four meters away from the machine then the sound pressure level will be about 94.8 decibels and this is pretty high sound pressure level. If a person is exposed to this high sound pressure level for sustain period of time, he will have serious hearing damage. So, to mitigate that a partition has been introduced, a wall and the transmission loss of this wall is 30 decibels. So, our next step is to compute the sound pressure level at a point; 1.5 meters away; in the operator room. So, our next step will be to compute L_{p2} .

(Refer Slide Time: 03:29)

Handwritten mathematical derivation for L_{P2} calculation:

$$= 105 + 10 \log_{10} \left[\frac{4}{47.37} + \frac{4}{4\pi \times 16} \right] + 0.1 \quad \alpha_1 = 4 \text{ m}$$

$$= 94.8 \text{ dB.}$$

$$L_{P2} = L_w - 10 \log_{10}(R_1) + 10 \log_{10} \left[\frac{4 S_w}{R_2} + 1 \right] - TL + 0.1$$

$$= 105 - 10 \log_{10}(47.37) + 10 \log_{10} \left[\frac{4 \times 16}{53.85} + 1 \right] - 30 + 0.1$$

$$= 61.7 \text{ dB}$$

$94.8 \rightarrow 61.7 \quad 94.8 - 61.7 = 33.1 \text{ dB}$

$TL \rightarrow 30 \text{ dB}$

Now, we know that the relation for L_{P2} can have two possible relations; the first if you go back to our problem.

(Refer Slide Time: 03:42)

Handwritten mathematical derivation for L_{P2} with conditional relations:

GIVEN L_w , WHAT IS L_{P2} ?

$$L_{P2} = L_w - 10 \log_{10}(R_1) + 10 \log_{10} \left(\frac{4 S_w}{R_2} + 1 \right) - TL + 0.1 \quad \text{if } \alpha_2 < \sqrt{\frac{S_w}{2\pi}}$$

$$L_{P2} = L_w - 10 \log_{10}(R_1) + 10 \log_{10} \left(\frac{4 S_w}{R_2} + \frac{S_w}{2\pi \alpha_2^2} \right) - TL + 0.1 \quad \text{if } \alpha_2 > \sqrt{\frac{S_w}{2\pi}}$$

$$L_{P1} = L_w + 10 \log_{10} \left(\frac{4}{R_1} + \frac{4}{4\pi \alpha_1^2} \right) + 0.1$$

If α_1 from 0.1 to 0.2 $R_1 \uparrow$ $L_{P2} \downarrow 1.5 \text{ dB}$
 $\downarrow 3.5 \text{ dB}$

α_2 from 0.1 to 0.2 $R_2 \uparrow$ $L_{P2} \downarrow 1.5 \text{ dB}$
 $\downarrow 3.5 \text{ dB}$

$\alpha_2 = 1.5 \text{ m}$
 $\sqrt{\frac{S_w}{2\pi}} = \sqrt{\frac{16}{2\pi}} = 1.596 \text{ m.}$

$\alpha_2 < \sqrt{\frac{S_w}{2\pi}}$

If R_2 is more than this parameter $S W$ divided by 2π ; then we use the first relation and if R_2 is; if it is less and if it is more then we use the second relation. So, let us calculate what is R_2 and then we will make a choice; whether we want to use the first relation or the second relation. So, R_2 equals 1.5 meters and $S W$ divided by 2π and $S W$ is the

surface area of the wall. So, that is equal to 16 divided by 2 pi and that is 1.596 meters, so what does that; that R 2 is less than S W divided by 2 pi.

So, if because that is the case; so we will use the first equation and that is equal to L w minus 10 log of R 1; plus 10 log 10, this is also base 10; 4 S W divided by R 2 plus 1, minus T L plus 0.1. So, L W is 105 minus 10 log of 10 of R 1 and my R 1 is 47.37; plus 10 log of 10; 4 S W. So, 4 times; S W is how much? 16 square meters; divided by the room constant; 53.85 plus 1 minus transmission loss, 30 plus 0.1 and that works out to be 61.7 decibels.

So, at this point; it is 61.7 DB and here it is how much? 94.8; now understand this, so from 94.8 to 61.7; most of the reduction in sound pressure level is happening because of this factor; because of transmission loss. So, what is the difference between 94.8 and 61.7; 94.8 minus 61.7 equals point, 1, 3, 3; 33.1 DB, there is a loss of 33.1 decibels and out of those 33 point decibels; transmission loss is responsible for 30 decibels in improving the sound pressure level and reducing the sound pressure.

The remaining three decibels are attributable to this parameter and this parameter. Bulk of the sound pressure level reduction is attributable to just this thing. So, the point what I am trying to make is; that the room constant helps makes things better. But if you have a partition in the wall and the thicker the wall is and the more rigid and the robust the wall is; that is going to be the predominant factor, which can really reduce your sound pressure level in the operating room or the adjacent room.

So, a lot of times; people in the operator room, I mean this is a very common problem; people ask that a lot of times their operator room is lined by this sound absorbing materials. And still they think that the sound level in the room is very high and they want to reduce the sound level. And a lot of time the question is that; if you increase the quality of the sound absorbing material in this room; Will that reduce the sound pressure level in this room significantly? And the question to that is; no, because bulk of the sound reduction does not happen because of absorption of sound by these materials, but rather because of the wall.

So, if you have the flexibility to make up more robust thicker, fatter, heavier wall; that will have a much better chance of reducing the overall sound pressure level in this room. So, this very important to understand that the transmission loss is a very significant

factor, which will help you reduce the sound pressure level in the operator room and this a very common problem.

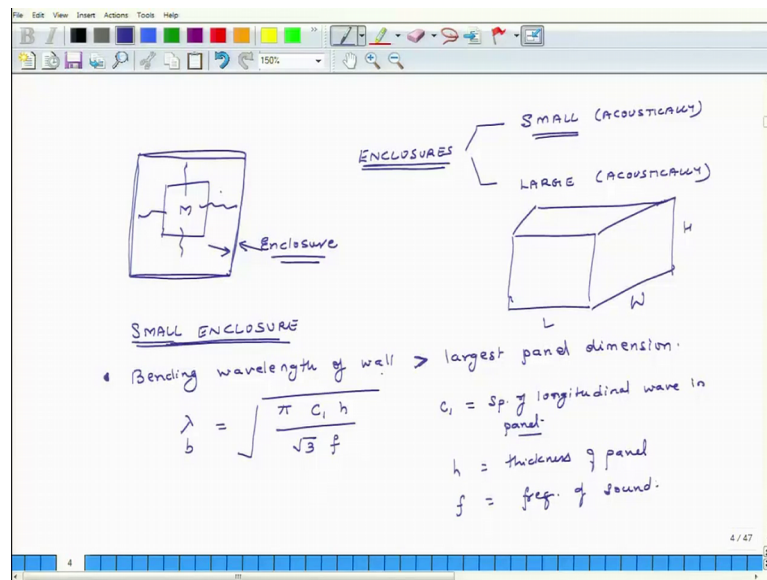

So, you may also be experiencing in your problem, in your particular industry and if this is the problem and if you have the flexibility to make the wall heavier and more robust; then go for it. So, this is our discussion for today; also I wanted to give you some understanding of what kind of reductions we can achieve, if we play with room constants.

So, we had seen that the sound pressure level in the second room is dependent on R_1 , it is also dependent on R_2 . So, here is some estimate; typically if you increase α_1 from 0.1 to 0.2; as α_1 increases, what will happen? R_1 will go up and as R_1 goes up; L_{p2} , and you keep everything else same and; then what you will find is that; if L_{p2} will go down by 1.5 DB, if you are using the first equation. And it will go down by 3.5 DB; if you are using the second equation.

So, if you double that sound absorption coefficient; your L_{p2} will reduce by one and half or three and half decibels; based on how far you are from the wall, so this is the case for α_1 . Same thing is also true for α_2 ; if you increase α_2 from 0.1 to 0.2; R_2 will go up and L_{p2} will also go down by 1.5 DB; if you are very close to the wall and it will go down by 3.5 DB; if you are far from the wall.

So, do not expect a lot of magic I mean of course, 3 DB is a significant reduction in the sound pressure level 3 and a half decibels. But we are expecting reductions; something like 10 DB, 20 DB, 30 DB; then it is important to figure out, how can you seal of this area, where there are noise making machines and you can have a partitioned room.

(Refer Slide Time: 12:58)

So, that concludes our discussion; the next topic we are going to discuss today or we are going to introduce today is acoustic enclosures. So, what is an acoustic enclosure? So suppose, you have a noise making machine. So, it is generating a lot of; it is radiating a lot of noise; one way to control the noise reduced by this machine is; by enclosing this machine itself in an enclosure.

You can enclose this machine in a covering; this covering may have some holes, may not have some holes; it all depends what kind of needs are there. But if you encase it into an enclosure, the amount of noise which will leak out to the outside; it will be only through this; if it is perfect enclosure with no openings then only vibro-acoustic noise will be able to get out.

Now, these encloses how much noise do they stop? Depends on their size, so there are small enclosures and by small I mean; acoustically and large enclosures, again this is acoustically; large enclosures. So, what we will discuss today are small enclosures and maybe next week we will talk also about large enclosures, but we will discuss today small enclosures and will also do an example on that. So, what is a small enclosure? So, an enclosure is acoustically small; if it meets the following two conditions.

So, the first condition is that the bending wavelength of wall is large compared to largest panel dimension. So, we will explain that; so this is the first condition it has to meet. So, what is the bending wavelength of the wall? So, this enclosure is made up of several

walls; it could be a cubical box or a box with 6 sides or it could be in a sphere or in a cylinder, but regardless whenever you are having an enclosure; it will have some walls outside it.

And when the sound from inside hits it; what will happen to the walls? They will try to vibrate; the walls will try to vibrate and when they are vibrating, they will be bending; they will not do this, they will be doing this. When something vibrates, when this is going to vibrate; it will not just do this, it will also do this. So, the walls are going to bend; they are going to bend and this bending phenomena is associated with wavelength.

So, the bending wavelength of the wall should be larger than the largest panel dimension. So, suppose this is an enclosure and let us say this is the largest panel dimension. So, this is W L height and this is the enclosure; maybe in this case largest panel dimension is W . So, the bending wavelength of the wall should be larger than the largest panel dimension. So, this is one and how do you figure out bending wavelength? We will discuss that.

So, what is bending wavelength? λ_b equals π times C_1 ; h divided by square root of 3 times frequency, where C_1 is the speed of longitudinal wave in panel. So, sound travels in air; similarly sound travels in water, similarly sound can travel in solids also; the phenomena is similar, but in solids it not only travels in longitudinal way or wave, but it also can travel in different ways.

So, in air the transmission of sound is like this, but in solids it can move like this, but it can also move like this. So, this is the speed of longitudinal wave in the panel; h is the thickness of panel and f is the frequency of sound. So, if the machine is just generating a single frequency; then we will calculate the bending wavelength associated with that frequency. If it is generating a lot of frequencies, then we will complete the smallest possible wavelength associated with largest frequency and then we will see whether that smallest wavelength is more than largest panel or not; if it is more than; it is, it meets our condition.

(Refer Slide Time: 20:05)

Bending wavelength of n :

$$\lambda_b = \sqrt{\frac{\pi c_1 h}{\sqrt{3} f}}$$

c_1 = Sp. of longitudinal wave in panel.
 h = thickness of panel.
 f = freq. of sound.

Wavelength of sound \gg Interior dimension of enclosure.

$$\frac{L_{\max}}{\lambda} = \frac{L_{\max} f}{c} < 0.1$$

So, this is the first condition; that the enclosure is small and there is another condition. The other condition is; that wavelength of sound is very large; compared to interior dimension of enclosure, it is very large. So, for practical purposes; we can say that L_{\max} , L_{\max} is the largest dimension of the enclosure divided by λ and that is; what is λ ? So, L_{\max} and λ is what? f over c and that is small compared to 0.1.

So, if it is 10 times; the ratio is 10 times or more then we say that this is the case. So, the point is; that an enclosure is small, if it meets this condition as well as this condition. If it does not meet either one of those condition, then we will not consider it to be small. So, this provides us the context for small acoustical enclosures and what we will do tomorrow is; we will conclude our discussion on small acoustic enclosures.

We will see what kind of sound transmission loss we can achieve; through small acoustical enclosures. And we will also hopefully try to do numerical example so that we learn something practical about it. So, once I again thank you for your time and we expect that you will be here tomorrow for the concluding part of this week.

Thank you and have a great day bye.
