Lecture - 53
Beam (two term solution)

Hello. Welcome to advanced composites. Today is the fifth day of the ongoing week which is the ninth week of this course. Last 3 days we have been discussing the principle of virtual work and how it can be used as a powerful method to solve problems related to deflections in composite plates; where the analytical solution may not necessarily be either available or it may be non-obvious.

Today we will continue this discussion, and we will solve the problem in context of a beam, but here we will not have just one term solution, but a multiple term solution. And we will see how we can have multiple that is a series solution for deflections and we will illustrated through the example of a beam which is isotropic, and pinned at both ends not simple both ends

(Refer Slide Time: 01:20)

BEAM (Two Term Solution)

$$EI \frac{d^4 w}{dx^4} - q_0 = 0$$

Diagram: A beam of length l is shown with a distributed load q_0 acting downwards. The beam is pinned at both ends, $x = -l/2$ and $x = l/2$. Boundary conditions are $w = 0$ and $M = 0$ at $x = \pm l/2$.

① $w_0(x) = A_1 \cos \frac{\pi x}{l} + A_3 \cos \frac{3\pi x}{l}$ $w = 0$ at $x = \pm l/2$

② $\#(x) = EI \left[A_1 \left(\frac{\pi}{l} \right)^4 \cos \frac{\pi x}{l} + A_3 \left(\frac{3\pi}{l} \right)^4 \cos \frac{3\pi x}{l} \right] - q_0$

③ VIRTUAL DISP. $w_1(x) = A_1 \cos \frac{\pi x}{l} + A_3 \cos \frac{3\pi x}{l}$: Satisfies $w_1 = 0$ @ $x = \pm l/2$

④ $\int_{-l/2}^{l/2} \left\{ EI \left[A_1 \left(\frac{\pi}{l} \right)^4 \cos \frac{\pi x}{l} + A_3 \left(\frac{3\pi}{l} \right)^4 \cos \frac{3\pi x}{l} \right] - q_0 \right\} \cdot \left\{ A_1 \cos \frac{\pi x}{l} + A_3 \cos \frac{3\pi x}{l} \right\} dx = 0$

So, we will generate the solution for a beam for 2 term solution. So, if we know how to do 2 we can do 3 4 term or whatever. So, we will generate a 2 term solution, and once again the beam is simply supported on both sides. So, beam axis is at the centre. So, this is my x axis, this is my z axis and I am interested in finding out the deflections for the

beam. The beam is again experiencing uniformly distributed normal load; which is q Newton per meters (Refer Time: 02:20)

The length of the beam is L . So, this is minus L over 2 and this is plus L over 2. What are the boundary conditions? The boundary condition is that w is equal to 0 at this end and also the moment is 0 at this end and w is 0 at this end, and the moment is 0 at this end, because it is simply supported on both the points. And to remind you, if we use virtual work, then we will only worry about the kinematic boundary conditions; that is boundary conditions which relate to displacement and slopes, not related it does not relate to a kinematic boundary condition, do not relate to forces and moments. So, we will worry only about w is equal to 0 at both ends.

Before we do that ok; so, what is the governing differential equation? The differential equation for the system is $EI \frac{d^4 w}{dx^4} - q$ is equal to 0. This is the governing differential equation; we have seen this earlier. And we will say that the displacement is having 2 terms $A_1 \cos \frac{\pi x}{L}$ plus another term $A_3 \cos \frac{3\pi x}{L}$. So, this we have chosen this function, this function W is equal to 0 at x is equal to minus both plus and minus L over 2. So, this function satisfies both the kinematic boundary conditions. So, we are fine with this function ok. So, this was a step one.

The next step is that we have to find the error, error force; error and here it is only a function of x is if I plug this w back into the governing differential equation. So, this is equal to $EI A_1 \frac{\pi^4}{L^4} \cos \frac{\pi x}{L} + A_3 \frac{3^4 \pi^4}{L^4} \cos \frac{3\pi x}{L} - q$. This is the error oh, I am sorry this q has to be outside the bracket. So, this is the error or the residue.

Third we have to write the statement for virtual work is equal to 0, and for that we have to first select a function for virtual displacement. So, virtual displacement now here is the trick, in the function for w there are 2 terms. So, we and what are unknowns? The unknowns are A_1 and A_3 . So, when we choose the error the function for displacement, there also we choose a 2 term virtual displacement field. That will make things easier.

So, virtual displacement is $W_1(x)$, and again we use the Galerkin method special Galerkin method. So, we use similar functions. So, this is equal to $A_1 \cos \frac{\pi x}{L} + A_3 \cos \frac{3\pi x}{L}$. I am sorry, A_3 so, this extra subscript implies that it is virtual displacement, $\cos \frac{3\pi x}{L}$. And we have to make sure that this virtual

displacement fields satisfies all the kinematic boundary conditions. Because this function is same as the actual displacement field, it satisfies all the kinematic boundary conditions. So, satisfies W is equal to 0 at x is equal to plus minus L over excuse me over 2 so, that is there.

So, the last step is now we say that we have to compute the virtual work and equate it to 0. So, what is virtual work? It is error force times virtual displacement integrated over the domain.

(Refer Slide Time: 07:57)

The slide shows the following handwritten equations:

$$\textcircled{3} \quad \text{VIRTUAL WORK}$$

$$\textcircled{4} \quad \int_{-L/2}^{L/2} \left\{ EI \left[A_1 \left(\frac{\pi}{L} \right)^4 \cos \frac{\pi x}{L} + A_3 \left(\frac{3\pi}{L} \right)^4 \cos \frac{3\pi x}{L} \right] - q_0 \right\} \cdot \left\{ A_1 \cos \frac{\pi x}{L} + A_3 \cos \frac{3\pi x}{L} \right\} dx = 0$$

$$\Rightarrow \int_{-L/2}^{L/2} \left\{ EI A_1 \cos \frac{\pi x}{L} \left[A_1 \left(\frac{\pi}{L} \right)^4 \cos \frac{\pi x}{L} + A_3 \left(\frac{3\pi}{L} \right)^4 \cos \frac{3\pi x}{L} \right] - q_0 \left\{ A_1 \cos \frac{\pi x}{L} + A_3 \cos \frac{3\pi x}{L} \right\} \right\} dx = 0$$

So, minus L over 2 to L over 2 $EI A_1 \pi$ over L to the power of 4 cosine πx over L plus $A_3 3 \pi$ over L 4 cosine $3 \pi x$ over L minus q naught. This is the error times parameter of a smallness which is ϵ times virtual displacement field $A_1 \cos \pi x$ over L plus $A_3 1 \cos 3 \pi x$ over L dx . And this is the overall virtual works. So, it has to become 0 as per the principle of virtual work.

Now, what we do is, we have a multiple of virtual work with respect to error force, and we reorganise these things. So, so what I get is minus L over 2 to L over 2. And first I multiply everything inside, and I collect all the parameters which are multiplied by A_1 , ok. So, $\epsilon A_1 1 \cos \pi x$ over L times $EI A_1 \pi$ over L to the power of 4 cosine πx over L plus $A_3 3 \pi$ over L to the power of 4 cosine $3 \pi x$ over L minus q naught. So, dx so, this is one integral plus minus L by 2 to L by 2, $\epsilon A_3 1 \cos 3 \pi x$ over L $EI A_1 \pi$ over L to the power of 4 cosine πx over L , plus $A_3 3 \pi$ over L 4

cosine $3\pi x$ over L minus q naught dx is equal to 0. So, I just reorganise whatever was there in the integral into 2 separate integrals that is all I have done.

Now, what I will do is, I will move this integral sign. So, I will take the epsilon A_{11} out.

(Refer Slide Time: 11:51)

The image shows a handwritten derivation on a whiteboard. It starts with two integrals, I_1 and I_2 , which are separated from a larger expression. The first integral, I_1 , is defined as $\int_{-L/2}^{L/2} \cos \frac{\pi x}{L} \left\{ EI \left[A_1 \left(\frac{\pi}{L} \right)^4 \cos \frac{\pi x}{L} + A_3 \left(\frac{3\pi}{L} \right)^4 \cos \frac{3\pi x}{L} \right] - q_0 \right\} dx$. The second integral, I_2 , is defined as $\int_{-L/2}^{L/2} \cos \frac{3\pi x}{L} \left\{ EI \left[A_1 \left(\frac{\pi}{L} \right)^4 \cos \frac{\pi x}{L} + A_3 \left(\frac{3\pi}{L} \right)^4 \cos \frac{3\pi x}{L} \right] - q_0 \right\} dx$. These are then combined into a single equation: $\epsilon A_{11} I_1 + \epsilon A_{31} I_2 = 0$. Below this, it is noted that $I_1 = 0$ and $I_2 = 0$ because A_{11} and A_{31} are arbitrary.

Like this, and I will do the same thing to the second integral. Because A_{31} and A_{11} they are constants. And I call this entire integral I_1 and I call this entire integral I_2 . So, essentially what I get is $\epsilon A_{11} I_1 + \epsilon A_{31} I_2 = 0$.

Now, this relation this A_{11} and A_{31} they are arbitrary numbers, they can be anything they can be anything. So, for this relation to be true, the first term has to be individually 0 and the second term has to be individually 0. Because A_{11} and A_{31} are arbitrary numbers, they can be anything and they are not 0.

So, what that means is that, I_1 should be 0 and I_2 should be 0. Because A_{11} and A_{31} are arbitrary, they can be anything, ok. But this equation has to be true for all values of A_{11} and A_{31} . So, it can be true only if I_1 is individually 0 and I_2 is individually 0.

Now, if you look at I_1 you get basically you get an equation in A_1 and A_3 . And if you look at I_2 you get another equation in A_1 and A_3 , ok. So, you get 2 equations with 2 unknowns. So, basically you will get when you solve this I_1 and I_2 and you reorganise, you will get a 2 by 2 equations system and this is how it will become, ok.

(Refer Slide Time: 14:16)

The image shows a handwritten derivation on a whiteboard. At the top, there is a boxed equation: $\epsilon A_{11} I_1 + \epsilon A_{31} I_2 = 0$. Above this box, there are some scribbles including ϵA_{31} , -42 , and I_2 . Below the box, it says $I_1 = 0$ and $I_2 = 0$. To the right of these, it says "Because A_{11} and A_{31} are arbitrary." Below this, there is a matrix equation:
$$\begin{bmatrix} \cdot & \cdot \\ \cdot & \cdot \end{bmatrix} \begin{Bmatrix} A_{11} \\ A_{31} \end{Bmatrix} = \begin{Bmatrix} \cdot \\ \cdot \end{Bmatrix}$$
 The matrix on the left is labeled "Stiffness matrix" and the vector on the right is labeled "force vector".

So, you will have a 2 by 2 matrix multiplied by vector $A_1 A_3$, and on the right side left right side you will have another matrix. So, this is called the stiffness matrix, and this is called the force vector. And A_1 and A_3 are amplitudes of the displacement component, right.

What is the first component? First component is A_1 the cosine πx over L , second component is A_3 cosine $3\pi x$ over L . So, you solve for these and you get A_1 and A_3 , ok. So, all it requires a just basic algebra integral calculus, and these are simple function. So, it is not difficult to integrate them at all. So, once you do that you get the values are A_1 and A_3 .

(Refer Slide Time: 15:41)

The slide shows handwritten mathematical derivations for a beam deflection problem. At the top, the constants A_1 and A_3 are defined as $A_1 = \frac{4}{\pi^5} \frac{q_0 L^4}{EI}$ and $A_3 = -\frac{A_1}{35}$. Below this, the deflection function $w^0(x)$ is given as $w^0(x) = \frac{4}{\pi^5} \left[\cos \frac{\pi x}{L} - \frac{1}{35} \cos \frac{3\pi x}{L} \right]$, with a note " \leftarrow 2-TERM SOL.". At the bottom, the values of $w^0(0)$ are compared for different solutions: $0.01302 \frac{q_0 L^4}{EI}$ (labeled "2-TERM"), $0.01309 \frac{q_0 L^4}{EI}$ (labeled "1-TERM"), and $0.01302 \frac{q_0 L^4}{EI}$ (labeled "EXACT"). A bracket groups these three results.

And the results are A_1 is equal to 4 over, excuse me, pi to the power of 5 $q_0 L^4$ divided by EI , and A_3 is equal to a 1 by 35 negative of that result what we find out. So, $w^0(x)$ is equal to 4 over pi to the power of 5 cosine pi x over L minus 1 over 35 cosine 3 pi x over L. So, this is the 2 term solution.

Similarly, if we wanted to do a 3 term solution, what will we do? We will go back to our expression for w^0 , we will have 3 terms maybe I just extend this. So, I will say A_1 cosine pi x over L plus A_3 cosine 3 pi x over L plus A_5 cosine 5 pi x over L. So, I will have 3 terms.

Next I will compute the error force, then I will have my virtual displacement. And in virtual displacement again I will have 3 terms, involving A_1 , A_3 , and A_5 , and then I equate the virtual work to get 0. And then here I have 2 equations involving A_1 and A_3 , there I will get 3 equations. And I solve for A_1 , A_3 , and A_5 and that is so I do it. So, this is the thing and just for comparison purposes, w^0 at 0 which is the origin is equal to $0.01302 \frac{q_0 L^4}{EI}$, this is the 2 term solution. And it is $0.01309 \frac{q_0 L^4}{EI}$ this is the one term solution and it is $0.01302 \frac{q_0 L^4}{EI}$ this is an exact solution.

So, we see that in this case, just by having 2 terms the midpoint deflection of the beam is pretty close to the actual value at least up to 4 places of decimal just by having 2 terms. So, this is the overall approach, and we can use a very similar

approach for plate also. So, that is what I plan to do today we will continue this discussion tomorrow as well.

Thank you.
