Lecture-37
Turbulence (contd...)

Welcome back, Let us continue the discussion on the turbulence scaling. So, we are looking at the effect of buoyancy and we derived the governing equations like continuity momentum and temperature equation and we have seen the extra term which comes because of due to the effect of buoyancy.

(Refer Slide Time: 00:39)

Turbulence

$$-\overline{w\theta'} = \Gamma_+ \frac{\partial \bar{\theta}}{\partial z}$$

$$\Gamma_+ = \frac{\nu_t}{\sigma_t}$$

$$\frac{g}{\theta_0} \overline{w\theta'} = -\frac{g}{\theta_0} \Gamma_+ \frac{\partial \bar{\theta}}{\partial z} > 0$$

\Rightarrow buoyant production

$$\frac{g}{\theta_0} \overline{w\theta'} = -\frac{g}{\theta_0} \Gamma_+ \frac{\partial \bar{\theta}}{\partial z} < 0$$

= buoyant destruction

INDIAN INSTITUTE OF TECHNOLOGY KANPUR

Ashoke De 162

Now, we are looking at the buoyancy production and destruction. This is the one if you have a parallel plate and then this part is where you get buoyant production and this is the buoyant destruction. Now, we can look at for this plane channel flow. This is a plane channel flow we can look at the buoyancy verses shear, so buoyancy versus shear. So now, turbulent kinetic energy budget for this fully developed plane channel flow with equal heat flux.

(Refer Slide Time: 01:00)

Turbulence

buoyancy vs shear

$$0 = -u'w' \frac{\partial \bar{u}}{\partial z} + \frac{g}{\theta_0} w'\bar{\theta}' + \frac{\partial}{\partial z} \left(-w' \frac{1}{2} u_i'^2 - \frac{1}{\rho} p'w' + v \frac{\partial x}{\partial z} \right) - \nu \left(\frac{\partial u_i'}{\partial x_i} \right)^2$$

$$0 = \frac{g w'\bar{\theta}'}{\theta_0} (1 - R_{if}) + \frac{\partial}{\partial z} \left(-w' \frac{1}{2} u_i'^2 - \frac{1}{\rho} p'w' + v \frac{\partial x}{\partial z} \right) - \nu \left(\frac{\partial u_i'}{\partial x_i} \right)^2$$

$R_{if} = \frac{g w'\bar{\theta}' / \theta_0}{u'w' \frac{\partial \bar{u}}{\partial z}} = \text{Richardson number}$
 $R_{if} < 0$: buoyant prod. , $R_{if} > 0$: dest.

$$\frac{d\bar{p}}{dx} \quad \bar{u} \rightarrow \quad z \uparrow \quad \downarrow g$$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 163

And bottom and top we get like

$$0 = -u'w' \frac{\partial \bar{u}}{\partial z} + \frac{g}{\theta_0} w'\bar{\theta}' + \frac{\partial}{\partial z} \left(-w' \frac{1}{2} u_i'^2 - \frac{1}{\rho} p'w' + v \frac{\partial x}{\partial z} \right) - \nu \left(\frac{\partial u_i'}{\partial x_i} \right)^2$$

So, this we can rewrite in a different form like

$$0 = -u'w' \frac{\partial \bar{u}}{\partial z} (1 - R_{if}) + \frac{\partial}{\partial z} \left(-w' \frac{1}{2} u_i'^2 - \frac{1}{\rho} p'w' + v \frac{\partial x}{\partial z} \right) - \nu \left(\frac{\partial u_i'}{\partial x_i} \right)^2$$

So, this particular term one can see is in this is where

$$R_{if} = \frac{\frac{g w'\bar{\theta}'}{\theta_0}}{u'w' \frac{\partial \bar{u}}{\partial z}} = \text{Richardson Number}$$

So, one can also categorize if R_{if} less than 0. Then we get buoyant production and if R_{if} greater than 0 you get destruction, buoyant destruction. Now net turbulent kinetic energy production if R_{if} greater than 1 which is the upper bound of that. Now, you can see this effect of buoyancy on overlap region.

(Refer Slide Time: 03:56)

So, you can think about this is an atmospheric boundary layer, where in the overlap region is the region between your inner layer and outer layer. So, the turbulence shear stress can be approximated at shear stress, basically this is shear stress at earth's surface which can be

$$-\rho \overline{u'w'} \approx \text{Shear stress at earth's surface} \equiv \rho u_\tau^2$$

$$-\rho C_p \overline{w'\theta'} \approx \text{Heat flux at earth's surface} \equiv \rho C_p F_{\theta_s}$$

Now, if the buoyant effect on mean velocities small which is a neutral boundary layer case then the mean velocity in overlap region one can write

$$\frac{z}{u_\tau} \frac{\partial \overline{u}}{\partial z} = \frac{1}{\kappa} \Rightarrow -\overline{u'w'} \frac{\partial \overline{u}}{\partial z} \approx \frac{u_\tau^3}{\kappa z}$$

by $u_\tau \frac{\partial \overline{u}}{\partial z} = \frac{1}{\kappa}$.

Now, in this case, the flux Richardson Number in overlap region will be equal to

$$R_{if} = \frac{g \overline{w'\theta'}/\theta_0}{\overline{u'w'} \frac{\partial \overline{u}}{\partial z}} = \frac{g F_{\theta_s}}{u_\tau^3/\kappa z} = \frac{z}{L}$$

where

$$L = \frac{u_\tau^3}{\kappa g [F_{\theta_s}/\theta_0]}$$

which is also called obukhov length. So that's how you can get these things.

(Refer Slide Time: 06:10)

Turbulence

Influence buoyancy on overlap region: atmospheric boundary layer (II)

- If buoyancy effect on mean flow is not small, then an additional dimensionless group appears for scaling of mean velocity gradient in overlap region:

$$\frac{z}{u_\tau} \frac{\partial \bar{u}}{\partial z} = \Phi \left(\frac{z}{L} \right) \quad \text{Monin-Obukhov similarity}$$

where $\frac{z}{L} = \frac{g F_{0z} / \theta_0}{u_\tau^3 / \kappa z}$ \propto $\frac{\text{buoy. prod./destr.}}{\text{shear prod.}}$

- Buoyant destruction if $L > 0$.

$$\rightarrow \Phi = \frac{1}{\kappa} \left(1 + 4.7 \frac{z}{L} \right) \Rightarrow \frac{\bar{u}}{u_\tau} = \frac{1}{\kappa} \ln \left(\frac{z}{z_0} \right) + \frac{4.7 z}{\kappa L}$$

- Buoyant production if $L < 0$.

$$\rightarrow \Phi = \frac{1}{\kappa} \left(1 - 15 \frac{z}{L} \right)^{-1/4}$$

(From: Businger et al., JAS, 1971)

Now, similarly, one can look at the buoyancy effect on overlap region which is an atmospheric boundary layer II. Now, if the buoyant effect on mean flow is not small so, previous case we said it is small then an additional dimension less group appears. So, which is like

$$\frac{z}{u_\tau} \frac{\partial \bar{u}}{\partial z} = \Phi \left(\frac{z}{L} \right)$$

this is how are z by L essentially the buoyant production or destruction to the shear production so, that is the ratio is the z by L.

Now, if L greater than 0 it is an buoyant destruction because your phi becomes

$$\Phi = \frac{1}{\kappa} \left(1 + 4.7 \frac{z}{L} \right)$$

where using that you can get the mean velocity profile like that and if L less than 0 this is a production. So one can plot this, in this axis is ratio z/L and look at these function and see how this actually varies. Now, another situation which may appear is the neutral atmospheric boundary layer where you can have this limit phi by z/L would be 1/kappa in overlap region. Now, typically atmospheric boundary layer this length scale is quite high.

(Refer Slide Time: 07:21)

Turbulence

ABL (10)

Neutral ABL

$$\lim_{z/L \rightarrow 0} \varphi\left(\frac{z}{L}\right) = \frac{1}{K} \quad \text{in overlap region}$$

ABL: $|L| > 10m$ for $z < 1m$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 166

So, the atmospheric conditions are approximately neutral for z less than 1 meter so, if that is the situation one can. Now we go recap our statistical description where we had this RANS equations. This is continuity, this is momentum and this is Reynolds system. Now here we got 1 continuity equation, 3 momentum equation or 3 component of the moment equation so, total we get 4 equations but we got here total 10 unknowns like P, u_i, u_i u_j prime physically 3 velocity component 1 pressure component 4 plus 6 reynolds stress component.

(Refer Slide Time: 08:10)

Turbulence

RANS

① — $\frac{\partial \bar{u}_i}{\partial x_i} = 0$

② → $\frac{\partial \bar{u}_i}{\partial t} + \bar{u}_j \frac{\partial \bar{u}_i}{\partial x_j} = -\frac{1}{\rho} \frac{\partial \bar{p}}{\partial x_i} + \nu \frac{\partial^2 \bar{u}_i}{\partial x_j^2} - \overline{\frac{\partial u_i u_j'}{\partial x_j}}$

4- eqs ⇒ 10 unknowns : $\bar{p}, \bar{u}_i, \overline{u_i u_j'}$

(1)
(3)
(6)

Closures

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 167

This is 6 component, this is 3 and this is 1. So, total it lead to 10 unknowns. So, we need closures otherwise, we cannot solve this system of equation. Now, if we rewrite the Reynolds stress term that is

Turbulence

Recap of statistical description of turbulence

• Turbulent viscosity has dimension: velocity * length
 • From figure it can be anticipated that: $\nu_t \sim u_0 l_0 \sim UL$
 scales of large eddies (are most efficient in mixing)

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 169

And this is if you scales of the mean flow is should be of U and L . So, it is actually the eddies viscosity scales of the order of this velocity and length scale. Now, we can come to the sum of the hypothesis. So, in analogy with molecules stress allowed a closer look at the molecular using kinetic gas theory. So, if you consider a 1 dimensional velocity profile so, this is at the macroscopic level and this is what happens in the microscopic level the molecules. So macroscopic momentum flux across this plane is σ_{xy} , which would be proportional to $c n m$.

(Refer Slide Time: 11:48)

Turbulence

Turbulent-viscosity hypothesis (I)

• Is analogy with molecular stress allowed? A closer look at the molecular stress using **kinetic gas theory**. Consider a 1-dimensional laminar velocity profile:

• Macroscopic mom. flux across y-plane:
 $\sigma_{xy}(y) \propto \underbrace{\bar{c} n}_{\sim \text{number of collisions across y-plane per unit time and area}} \underbrace{m [u(y+\lambda) - u(y)]}_{\text{averaged transfer of x-mom. from collisions between molecules at } y+\lambda \text{ and } y}$

• Taylor expansion:
 $\sigma_{xy}(y) \propto \bar{c} n m \lambda \frac{\partial u}{\partial y} \left[1 + \frac{1}{2} \frac{\lambda}{L} + \dots \right]$
 with $L = \frac{\partial u / \partial y}{\partial^2 u / \partial y^2}$

λ : mean free path
 \bar{c} : mean molecular speed
 m : molecular mass
 n : number of molecules per unit volume

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 170

So, this is the number of collisions across y plan per unit time and area and these component contribute to averaged transfer of x momentum from collisions between molecule at $y + \lambda$ and y between this. So, using the taylor expansion one can write this sigma x y in terms of this and then lambda del u by del y where L is represented like this, here lambda is the mean free path,

c is the mean molecular speed, m is the molecular mass and n represents the Number of molecules per unit volume.

(Refer Slide Time: 13:06)

Now, in practical application typically λ is quite small than L which signifies that σ_{xy} would be

$$\sigma_{xy} = \rho \nu \frac{\partial u}{\partial y}$$

where ν is

$$\nu \approx \frac{1}{2} \bar{c} \lambda$$

now, for here you can have for example, here this λ is approximate 60 nanometer, \bar{c} is roughly 450 meter per second which gets you ν as 1.35×10^{-5} meter square per second. Now, then we get the model for turbulent viscosity where λ scales \bar{c} goes to u_0 where ν_t is scale like $u_0 l_0$.

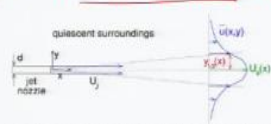

In general this l_0 is of the order of l for both boundary free or wall bounded flows. So that means, the turbulent mixing is non local. So this turbulent viscosity a hypothesis still it is provides an reasonable result in particular when production and viscous dissipation rate optic in local balance.

(Refer Slide Time: 14:36)

Turbulence

Turbulent-viscosity models (I)

- Simplest models: constant turbulent viscosity

$$v_t = U_0 y_{1/2} / Re_t$$

constant in y for self-similar plane jet

Limited range of applicability: boundary-free shear flows (lectures 6 and 7).
 Model is incomplete: value of Re_t sensitive to precise definitions of $U_0, y_{1/2}$.
 Model does not account for intermittency at edges of jet/wake/mixing-layer.

$$v_t = \gamma U_0 y_{1/2} / Re_t$$

intermittency = probability that at a fixed position \underline{x} the flow is turbulent (rotational)

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 172

Now, that will actually paves the way for building up the turbulent eddy viscosity or turbulent viscosity models. So simplest one can think about it is a constant turbulent viscosity. So, here simple jet like this, where

$$v_t = U_0 y_{1/2} / Re_t$$

So, this simplest one has a limited range of applicability, only boundary free shear flows. Now, model is incomplete value of Re_t sensitive to define U_0 and Y_0 and also it has does not account for the intermittency.

So, that is why the v_t if you taken factor for intermittency ahead of this which will look like this. So, this intermittency will give you the probability that at a fixed position x the flow is turbulent.

(Refer Slide Time: 15:35)

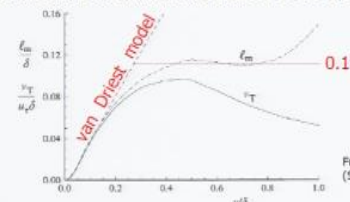

Turbulence

Turbulent-viscosity models (II)

- Prandtl's mixing-length model (1925): $v_t = l_m^2 |\partial \bar{u} / \partial y|$

Generalization by Smagorinski (1963): $v_t = l_m^2 \sqrt{2 \bar{S}_{ij} \bar{S}_{ij}}, \bar{S}_{ij} = \frac{1}{2} \left(\frac{\partial \bar{u}_i}{\partial x_j} + \frac{\partial \bar{u}_j}{\partial x_i} \right)$

Model used in analysis of wall-bounded shear flows (lectures 8 and 9).
 Model incomplete: mixing-length needs to be specified.

From DNS of turbulent plane boundary layer (Spalart, 1988).

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 173

So, some sort of an now, in 1925 way back the Prandtl's proposed the mixing length model, which is like

$$v_t = l_m^2 \left| \frac{\partial \bar{u}}{\partial y} \right|$$

and then later on in 1963 Smagorinsky generalize that v_t would be this

$$v_t = l_m^2 \sqrt{2 S_{ij} S_{ij}}$$

is where S_{ij} is the standard tensor and, you can look at this where this model can be and later on also Smagorinsky, use these hypotheses to derive the some other turbulence model.

(Refer Slide Time: 16:22)

Now, then the development move to an one equation model, where the model in which turbulent kinetic energy use to estimate characteristics velocity scale. So, this is the example of prandtl one equation model 1945 where v_t is approximated like this constant root of kinetic energy l_m and this is the kinetic energy equation that used to be solved, where these are the model coefficients. Now, this model has not good agreement with the DNS in outer layer of the turbulent plane channel flow, but it fails in viscous all region.

So, it is incomplete since mixing length has to be specified that means this particular term l_m which needs to be specified before and when you start your calculation, so, you need to specify that and which creates the problem here.

(Refer Slide Time: 17:21)

Now, later on, there is the development moved at and we have got two equations model where simple two equation model you solve k and epsilon model where kinetic energy and along with the dissipation where

$$\nu_t = C_\mu \sqrt{k} \left(\frac{k^{\frac{3}{2}}}{\varepsilon} \right) = C_\mu \frac{k^2}{\varepsilon}$$

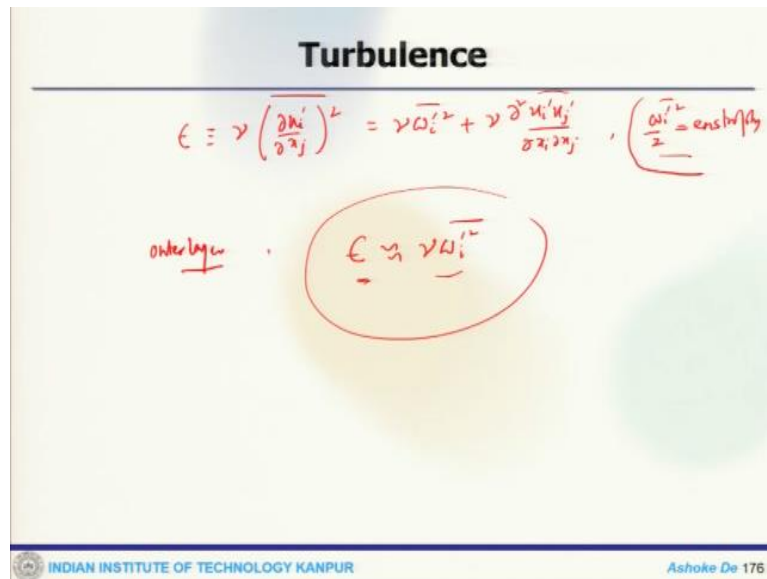

So, this was proposed by Johnson lauder in 1972 then different variant of like k Omega where do you solve for kinetic energy and the turbulent frequency.

In that case,

$$\nu_t = C_\omega \sqrt{k} \left(\frac{k^{\frac{3}{2}}}{\omega} \right) = C_\omega \frac{k}{\omega}$$

This is proposed by Wilcox in 1993. See, this two equation models are complete in the sense that no flow dependent specification like such as l_m is required. So, that way they look complete here do you solve for the kinetic energy or epsilon or the turbulent frequency. So, typically, these days event in the industrial application these models are quite heavily used.

(Refer Slide Time: 18:44)

Now, how we actually look at the relationship between discuss dissipation rate with the end stopping. So, viscous dissipation is given as

$$\epsilon \equiv \nu \overline{\left(\frac{\partial u_i'}{\partial x_j}\right)^2} = \nu \overline{\omega_i'^2} + \nu \frac{\partial^2 \overline{u_i' u_j'}}{\partial x_i \partial x_j}$$

where $\overline{\omega_i'^2}/2$ is the enstrophy So, the enstrophy is a measure of the. So, this actually the measure of the intensity of vorticity fluctuation. So, now one can see in the small scale you get to see the largest amount of this contribution of enstrophy.

And contribution of the turbulent kinetic energy at the large scale. Now, for wall bounded flows shear's flows wall bounded shear's flows outer layer you get this dissipation is some how connected with enstrophy like that. So, that means, that this equation can be approximated as equals for enstrophy there is a paradox from kolmogorov in 1941 that epsilon is actually determined by the energy transfer rate at large scale and in that it should be independent of viscosity , but when you look at these they are sort of correlated.

(Refer Slide Time: 20:32)

Turbulence

TKE:

$$\frac{\partial k}{\partial t} + \bar{u}_j \frac{\partial k}{\partial x_j} = P + \frac{\partial}{\partial x_j} \left(\left(\frac{\nu_t}{\sigma_k} + \nu \right) \frac{\partial k}{\partial x_j} \right) - \epsilon$$

$$\frac{\partial \epsilon}{\partial t} + \bar{u}_j \frac{\partial \epsilon}{\partial x_j} = \text{Prod} + \frac{\partial}{\partial x_j} \left(\left(\frac{\nu_t}{\sigma_\epsilon} + \nu \right) \frac{\partial \epsilon}{\partial x_j} \right) - \text{Diss}$$

Prod-Diss:

$$\frac{\epsilon}{k} (C_{\epsilon 1} P - C_{\epsilon 2} \epsilon)$$

If $P \uparrow \rightarrow k \uparrow \rightarrow$ TKE *transported down*
 $\frac{\nu_t}{\epsilon} \downarrow$ if $\epsilon \uparrow \rightarrow$ tends to decrease TKE

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 177

So, then we get the transport equation for epsilon where we got turbulent kinetic energy which is

$$\frac{\partial k}{\partial t} + \bar{u}_j \frac{\partial k}{\partial x_j} = P + \frac{\partial}{\partial x_j} \left(\left(\frac{\nu_t}{\sigma_k} + \nu \right) \frac{\partial k}{\partial x_j} \right) - \epsilon$$

similarly, we get the equation for epsilon which is

$$\frac{\partial \epsilon}{\partial t} + \bar{u}_j \frac{\partial \epsilon}{\partial x_j} = \text{Prod} + \frac{\partial}{\partial x_j} \left(\left(\frac{\nu_t}{\sigma_\epsilon} + \nu \right) \frac{\partial \epsilon}{\partial x_j} \right) - \text{Diss}$$

So, there is a production time there is a dissipation so, there are some empirical relation for that this defense of these 2 is approximated

$$\frac{\epsilon}{k} (C_{\epsilon 1} P - C_{\epsilon 2} \epsilon)$$

now, if p increases kinetic energy increases. So, turbulent kinetic energy transport down now energy cascade at timescale k by epsilon which will if your epsilon increases, so, which will tends to decrease turbulent kinetic energy. So, now, that a two equation model where you have k and epsilon.

(Refer Slide Time: 22:32)

Turbulence

k-ε model

$$\frac{\partial \bar{u}_i}{\partial x_i} = 0$$

$$\rightarrow \frac{\partial \bar{u}_i}{\partial t} + \bar{u}_j \frac{\partial \bar{u}_i}{\partial x_j} = -\frac{1}{\rho} \frac{\partial (\bar{p} + 2\rho k/3)}{\partial x_i} + \frac{\partial (2[v_i + \nu] \bar{S}_{ij})}{\partial x_j} \quad \text{with } \bar{S}_{ij} = \frac{1}{2} \left(\frac{\partial \bar{u}_i}{\partial x_j} + \frac{\partial \bar{u}_j}{\partial x_i} \right)$$

$$v_t = C_\mu \frac{k^2}{\varepsilon}$$

$$\rightarrow \frac{\partial k}{\partial t} + \bar{u}_j \frac{\partial k}{\partial x_j} = P + \frac{\partial}{\partial x_j} \left(\left[\frac{v_t}{\sigma_k} + \nu \right] \frac{\partial k}{\partial x_j} \right) - \varepsilon \quad \text{with } P = 2v_t \bar{S}_{ij} \bar{S}_{ij}$$

$$\rightarrow \frac{\partial \varepsilon}{\partial t} + \bar{u}_j \frac{\partial \varepsilon}{\partial x_j} = \frac{\varepsilon}{k} (C_{\varepsilon 1} P - C_{\varepsilon 2} \varepsilon) + \frac{\partial}{\partial x_j} \left(\left[\frac{v_t}{\sigma_\varepsilon} + \nu \right] \frac{\partial \varepsilon}{\partial x_j} \right)$$

Coefficients: $C_\mu = 0.09$, $\sigma_k = 1.0$, $\sigma_\varepsilon = 1.3$, $C_{\varepsilon 1} = 1.44$, $C_{\varepsilon 2} = 1.92$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 178

And if you put everything together this is what you need to solve in a RANS context where the first equation comes from the continuity second equation is your momentum this is for turbulent kinetic energy there P is the production of kinetic energy this is epsilon are these are some of the modern constants. So, that is a complete model. And now, this is quite I mean readily available in any commercial CFD package or code or also most of the code which are used by the academicians also simple to use, easy to implement and can be used for a wide range of flows with their limitations. So, one has to know the limitations.

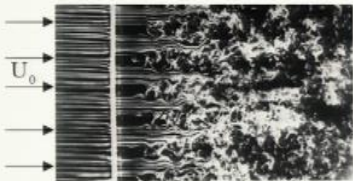

(Refer Slide Time: 23:27)

Turbulence

Coefficients in k-ε model (I)

- Coefficients in model have been determined by tuning model for various different flows.
- Decaying homogeneous turbulence: turbulence in absence of mean rate-of-strain => no production of TKE => turbulence vanishes.

Example: grid-generated turbulence (flow through perforated plate). Flow approximately homogeneous in frame moving with mean flow

$$\left. \begin{aligned} \frac{Dk}{Dt} &= -\varepsilon \\ \frac{D\varepsilon}{Dt} &= -C_{\varepsilon 2} \frac{\varepsilon^2}{k} \end{aligned} \right\} \begin{aligned} k(t) &= k_0 (t/t_0)^{-n} \\ \varepsilon(t) &= \varepsilon_0 (t/t_0)^{-(n+1)} \\ &\text{with } t = x/U_0, \\ t_0 &= n k_0 / \varepsilon_0 \\ &\text{and } n = 1/(C_{\varepsilon 2} - 1) \end{aligned}$$

(source: M. Van Dyke, Album of fluid motion) Experiments: $n \approx 1.3 \Rightarrow C_{\varepsilon 2} \approx 1.77$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 179

Now, if you look at those coefficients, which are present they are in the k-epsilon and model. So, they are been determined by tuning the model for different flows. Now, one important flow is the decaying homogeneous turbulence, so, turbulence is absence of mean rate of strain, so, there is no production turbulent kinetics energy turbulence vanishes. So, that is where these are

the coefficients are which are kind of looking at a different flows, these coefficients are tuned over a period of time and they are.

(Refer Slide Time: 24:04)

Turbulence

k-ε model

$$\frac{\partial \bar{u}_i}{\partial x_i} = 0$$

$$\rightarrow \frac{\partial \bar{u}_i}{\partial t} + \bar{u}_j \frac{\partial \bar{u}_i}{\partial x_j} = -\frac{1}{\rho} \frac{\partial (\bar{p} + 2\rho k/3)}{\partial x_i} + \frac{\partial (2[v_i + \nu] \bar{S}_{ij})}{\partial x_j} \quad \text{with } \bar{S}_{ij} = \frac{1}{2} \left(\frac{\partial \bar{u}_i}{\partial x_j} + \frac{\partial \bar{u}_j}{\partial x_i} \right)$$

$$v_i = C_\mu \frac{k^2}{\varepsilon}$$

$$\rightarrow \frac{\partial k}{\partial t} + \bar{u}_j \frac{\partial k}{\partial x_j} = P + \frac{\partial}{\partial x_j} \left(\left[\frac{v_i + \nu}{\sigma_k} \right] \frac{\partial k}{\partial x_j} \right) - \varepsilon \quad \text{with } P = 2v_i \bar{S}_{ij} \bar{S}_{ij}$$

$$\rightarrow \frac{\partial \varepsilon}{\partial t} + \bar{u}_j \frac{\partial \varepsilon}{\partial x_j} = \frac{\varepsilon}{k} (C_{\varepsilon 1} P - C_{\varepsilon 2} \varepsilon) + \frac{\partial}{\partial x_j} \left(\left[\frac{v_i + \nu}{\sigma_\varepsilon} \right] \frac{\partial \varepsilon}{\partial x_j} \right)$$

widely acceptable for large no. of flows

Coefficients: $C_\mu = 0.09, \sigma_k = 1.0, \sigma_\varepsilon = 1.3, C_{\varepsilon 1} = 1.44, C_{\varepsilon 2} = 1.92$

Now these coefficients are some how one can say widely acceptable for large number of flows. Having said that, one has to make a note here that any specific application this requires some tuning.

(Refer Slide Time: 24:32)

Turbulence

plane channel flow

$$u_\tau^2 \approx -\overline{v^2} = C_\mu \frac{k^2}{\varepsilon} \frac{\partial \bar{u}}{\partial y}$$

$$0 \approx P - \varepsilon$$

$$0 \approx \frac{\varepsilon}{k} (C_{\varepsilon 1} P - C_{\varepsilon 2} \varepsilon) + \frac{\partial}{\partial y} \left(\frac{v_i + \nu}{\sigma_\varepsilon} \frac{\partial \varepsilon}{\partial y} \right)$$

$$\approx -\frac{\varepsilon}{k} (C_{\varepsilon 2} - C_{\varepsilon 1}) \varepsilon$$

⇒ net sink

$\bar{u} \approx \frac{u_\tau}{k} \ln(y/\delta)$
 $C_\mu = \left(\frac{u_\tau}{k} \right)^2 \approx 0.09$
 $C_{\varepsilon 1} = C_{\varepsilon 2} - \frac{k^2}{\sigma_\varepsilon \sqrt{C_\mu}}$
 $R = 0.73 \Rightarrow$
 $C_{\varepsilon 1} = 1.44$

Now, behavior of this model in logarithmic layer for let us say plane channel flow. So, if you look at the behavior, so, u_τ^2 will be

$$u_{\tau}^2 = C_{\mu} \frac{k^2}{\epsilon} \frac{\partial \bar{u}}{\partial y}$$

this would be P – epsilon and

$$0 \approx \frac{\epsilon}{k} (C_{\epsilon_1} P - C_{\epsilon_2} \epsilon) + \frac{\partial}{\partial y} \left(\frac{v_t}{\sigma_t} \frac{\partial \epsilon}{\partial y} \right)$$

So, this term which will get back as

$$\approx (C_{\epsilon_1} - C_{\epsilon_2}) \epsilon$$

this is the turbulent diffusion term, diffusion transport Epsilon from one region towards a log region.

So, this would be Net sink term. So, using \bar{u} equals to

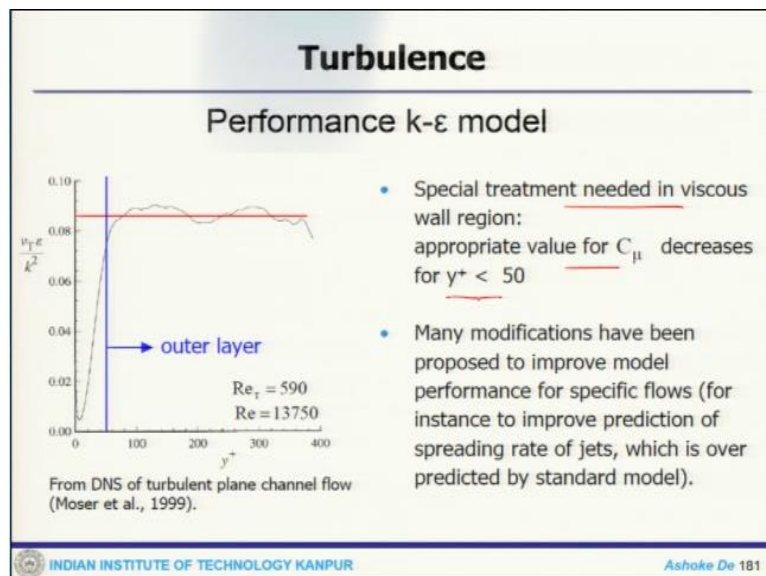

$$\bar{u} = \frac{u_{\tau}}{k} \ln \left(\frac{y}{y_0} \right)$$

$$C_{\mu} = \left(\frac{u_{\tau}^2}{k} \right)^2 \approx 0.09$$

$$C_{\epsilon_1} = C_{\epsilon_2} - \frac{k_1^2}{\sigma_t \sqrt{C_{\mu}}}$$

where for kappa equal to point 0.43 that gets you C_{ϵ_1} is 1.44 as I said these coefficients are widely acceptable.

(Refer Slide Time: 26:17)

Now, if you look at this performance of this model, so, you require special treatment in the viscous wall there are approximately value of similar decreases for y^+ less than 50 that plane is go to outer layer it is fine within that. So, lot of modification have been proposed people have looked at the experiments and huge set of DNS database of channel flow to look at what kind of modification to be made for this model to be accurately used in the that near all region. (Refer Slide Time: 26:57)

Turbulence

Reynolds-stress model (RSM)

- Idea: instead of using the Boussinesq hypothesis, solve transport equation for each Reynolds stress.
- Derivation of transport equation for Reynolds stress $\overline{u_i' u_k'}$:
 - subtract mean momentum equation from momentum equation
 - multiply momentum equation for u_i' with u_k'
 - similarly, multiply momentum equation for u_k' with u_i'
 - add two equations together and take Reynolds average

$$\frac{\partial \overline{u_i' u_k'}}{\partial t} + \overline{u_j} \frac{\partial \overline{u_i' u_k'}}{\partial x_j} = \underbrace{\left(-\overline{u_j' u_k'} \frac{\partial \overline{u_i}}{\partial x_j} - \overline{u_i' u_j'} \frac{\partial \overline{u_k}}{\partial x_j} \right)}_{\text{production}} + \underbrace{\frac{\partial}{\partial x_j} \left(-\overline{u_i' u_j' u_k'} - \frac{1}{\rho} \overline{u_i' p' \delta_{jk}} - \frac{1}{\rho} \overline{u_k' p' \delta_{ij}} + \nu \frac{\partial \overline{u_i' u_k'}}{\partial x_j} \right)}_{\text{turbulent+viscous transport}}$$

$$+ \frac{1}{\rho} \overline{p' \left(\frac{\partial u_i'}{\partial x_k} + \frac{\partial u_k'}{\partial x_i} \right)} - \underbrace{2\nu \overline{\frac{\partial u_i'}{\partial x_j} \frac{\partial u_k'}{\partial x_j}}}_{\text{viscous dissipation}}$$

pressure-strain term
viscous dissipation

Now, then, after that, there is another set of model which is called Reynolds stress model, which is slightly more involved. Here the whole idea is that instead of using Boussinesq hypotheses, we solve for the transport equation for each Reynolds stress. And now, each Reynolds stress means we get so, many equations for the 6 equation for these Reynolds stress and how do you opt in that equation, you subtract the mean momentum equation from the momentum or equation multiply momentum equation for u_i prime with u_k prime.

Similarly multiply moment equation for u_k prime and two equation together and once you take the Reynolds average this is what you get. So, this is your each Reynolds stress component and set it and so, this side you can think about the material derivative of that these 2 term all together contribute to the production and these can contribute to the turbulent viscous transport see the pressure term this is a pressure strain term and this is viscous distribution.

So, essentially your left hand side this is the material derivative of the Reynolds stress term or the stress component where right hand side you have production turbulence + viscous transport. So, if you look at compared to two equation models, this equation set of equations are quite

exhaustive. So, they are not that straight forward to be implemented, but, it has certain advantages over the two equation models.

(Refer Slide Time: 28:37)

So, like one can think about there is no closure which is required for production term, that is one of the important aspect of it, then, one can think about isotropic of the microstructure except close to the wall which can be approximated as

$$-2\nu \frac{\partial u'_i}{\partial x_j} \frac{\partial u'_i}{\partial x_j} \approx -\frac{2}{3} \epsilon \delta_{ix}$$

then there is a negligible contribution of microstructure to Reynolds shear stress. So, viscous dissipation rate of the Reynolds shear stress can be neglected.

Now, there are other closure problem. So, like turbulence transport that is one issue pressure strain term that is another problem because it is responsible for return to isotropic and destruction Reynolds stress term and also it is computationally expensive. So, we will see how I mean other terms that effect this Reynolds stress equation, stop there today and continue in the next lecture.
