**Compressible Flows (Contd.)**

(Refer Slide Time: 00:31)

We were discussing about the property variations in isentropic flows and let us work out a few problems to see that how we may evaluate those property variations. So, let us say that we have a tank like this to which is connected one manometer, this tank has air at 30 degree centigrade, pressure is not known, the exit state from the tank is with a velocity of 235 meter per second. The manometer has the manometric fluid as mercury with a density of 13,550 kg per meter cube.

The height that is the difference in the levels of the limbs; of the 2 limbs of the manometer is 30 meter, assume isentropic flow that is given, you have to find out what is the pressure of the tank and what is the exit pressure and what is the exit Mach number, okay. So, let us see how we may work out this problem, so if we apply the energy equation in terms of the stagnation temperature, we have seen that  $T_0 = T_e + \frac{u_e^2}{2 C_p}$ .

So, when you have this large tank, remember that the properties of fluid; the fluid which is there in the tank is approximately at a stagnation condition, so the temperature; the 30 degree centigrade the air temperature within this large tank, this is the stagnation temperature

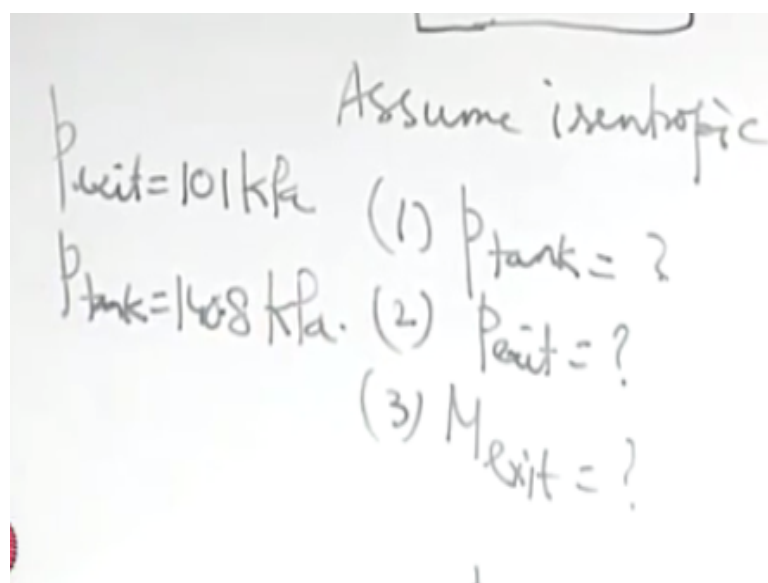

corresponding to this condition. So, you have  $T_0$  is  $273 + 30$  kelvin, so if you want to find out what is the exit temperature; so long as the flow is adiabatic one, you have  $T_e + \frac{u_e^2}{2C_p}$  is same as any  $T_e + \frac{u_e^2}{2C_p}$ .

So, you can use the exit state here, so let us say  $T_{exit}$  and  $u_{exit}$ ;  $u_{exit}$  is given as 235 meter per second, so from here you can find out what is  $T_{exit}$ . So, if you evaluate that this  $T_{exit}$  will come as 276 kelvin. From the  $T_{exit}$ , you can calculate the Mach number at the exit because the sonic speed at the exit is root over  $\gamma R T_{exit}$ . Remember that we are considering an isentropic flow for which this formula is valid.

So, from here you can have the Mach number at the exit is  $= u/c$  and if you calculate that it is approximately 0.706. So, when you calculate the Mach number, you can find out from that the expression of  $p/p_0$ , so remember that we had an expression of  $T/T_0$  or  $T_0/T$  rather, for an isentropic flow  $T_0/T$  was  $1 + \frac{\gamma - 1}{2} M^2$  and  $p_0/p$ ; so if we know the Mach number at the exit, so from here we can find out  $p_0/p_{exit}$  by using the Mach number at the exit.

And the remaining relationship between  $p_0$  and  $p_{exit}$ , so remember  $p_0$  is nothing but  $p$  at the tank, right. So, the other thing is the difference between the  $p$  at the tank and the  $p_{exit}$  or the  $p$  atmosphere; remember  $p_{exit}$  is same as the  $p$  atmosphere that is given from this manometer, so  $p_{tank} - p_{exit} = \frac{\rho_{air}}{\rho_{water}} h \cdot g$ , from the readings of the manometer. So, now you have 2 equations; one is  $p_0/p_{exit}$  that is as good as  $p_{tank}/p_{exit}$ .

**(Refer Slide Time: 06:59)**

Another is p tank - p exit, so from these 2 equations you may solve for the 2 unknowns; P tank and P exit, so the answer to this is P exit = 101 kilopascal approximately and P tank is = 140.8 kilopascal. Let us work out a second problem to illustrate the use of isentropic properties. So, this problem statement is like this; considered isentropic flow in a channel of varying area with the sections 1 and 2; between the sections 1 and 2.

**(Refer Slide Time: 07:49)**

$P_{\text{tank}}$      $M_1 = 2$      $\frac{V_2}{V_1} = 1.2$   
 Estimate: (1)  $M_2 = ?$   
               (2)  $A_2/A_1 = ?$   
               (3) converging/diverging?  
 Assume isentropic flow  
 $1.2 = \frac{V_2}{V_1} = \frac{C_2 M_2}{C_1 M_1} = \frac{\sqrt{\gamma R T_2} M_2}{\sqrt{\gamma R T_1} M_1} = \frac{M_2}{M_1} \sqrt{\frac{T_2}{T_1}} = \frac{M_2}{M_1} \sqrt{\frac{1 + \frac{\gamma-1}{2} M_1^2}{1 + \frac{\gamma-1}{2} M_2^2}}$   
 $M_2 = ? \Rightarrow M_2 = 2.92$

Given the Mach number at the section 1 is 2 and given that  $V_2/V_1$  is = 1.2 is given. What you have to estimate is the following number 1; Mach number at 2, number 2;  $A_2/A_1$  and number 3; figure out whether the channel is converging or diverging of course, it might appear to be trivial by looking into  $A_2/A_1$  but you also have to make sure that there is no other type of variation in between.

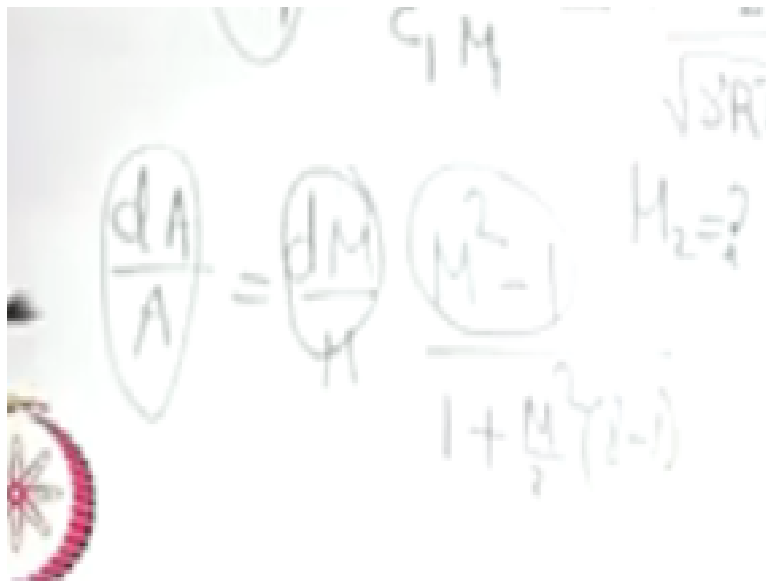

So, it has to be either monotonic or it may be area increasing and decreasing and so on, so just  $A_2/A_1$  is not sufficient to tell you that what is the total shape of the channel in between 1 and 2 that is why the third part of the question and the assumption is an isentropic flow. So, if you see what is given here is  $V_2/V_1$ , let us see that how we may express it in terms of our known quantities.

So,  $V_2/V_1$  is the sonic speed at 2 \*  $M_2$ / the sonic speed at 1 \*  $M_1$ , the sonic speed is square root of gamma at  $T_2$  because it is isentropic flow, so this is  $M_2/M_1$  8 square root of  $T_2/T_1$ , okay. Now,  $T_2/T_1$  may be expressed as  $T_2/T_0$  divided by  $T_1/T_0$ , remember  $T_1$  is; sorry,  $T_0$  is remaining fixed, this is the isentropic flow, so there is no question of any change of  $T_0$ , so you

can write this as; so if you write for example,  $T_0/T_1$ ;  $T_0/T_1$  is  $1 + \gamma - 1/2 M_1^2 / 1 + \gamma - 1/2 M_2^2$  square this whole thing to the power of  $1/2$  okay.

So, in this expression, what is given?  $V_2/V_1$  is 1.2,  $M_1$  is given, so you have to find out  $M_2$ , of course this is not a straightforward linear algebraic equation to find out but one may find out by trial and error or by using some software such as the engineering equation solver and so on. So, it is possible to find out  $M_2$  from this equation and if that is found out  $M_2$  turns out to be 2.98, this is by iterative solution.

**(Refer Slide Time: 11:59)**

The image shows a handwritten equation on a whiteboard. The equation is:

$$\frac{dA}{A} = \frac{dM}{M} \frac{M^2 - 1}{1 + \frac{\gamma}{2}(M^2 - 1)}$$

Other handwritten notes include  $\gamma M$  at the top,  $\sqrt{\gamma R T}$  on the right, and  $M_2 = ?$  next to the equation.

So, when you find out what is the value of  $M_2$ , so the Mach number at 1 is 2, Mach number at 2 is 2.98 and how the area is increasing, if you want to answer the third part; let us use the expression of  $dA/A$ , which we derived in the previous lecture, so let us just write that expression, see  $dA/A$  is this one, this is the expression that we derived in the previous lecture. So, if you see here, now the Mach number is between 2 and 2.98, so the  $M^2 - 1$  is positive.

**(Refer Slide Time: 12:54)**

$$\frac{A_2}{A_1} = \frac{\left(\frac{A_2}{A^*}\right) \rightarrow \text{from } M_2}{\left(\frac{A_1}{A^*}\right) \rightarrow \text{from } M_1} = 2.46.$$

Not only that  $M$  is increasing, so from 2 to 2.98, so  $dM/M$  is positive, the denominator is always positive that means,  $dA/A$  has to be positive, so it is an increasing  $A$ , it is a diverging section and how to find out what is the real value of  $A_2/A_1$ ? So,  $A_2/A_1$  is nothing but  $A_2/A^*$  divided by  $A_1/A^*$ , remember what is  $A^*$ ?  $A^*$  is the equivalent area at which sonic condition could be achieved under an isentropic process.

So, when the flow is isentropic,  $A^*$  does not change, if it is not isentropic the value of  $A^*$  will change. So,  $A_2/A^*$  and  $A_1/A^*$ ; these 2 may be found out again we have derived expressions for  $A/A^*$  as a function of Mach number, so from  $A_2/A^*$  value you can find out because you know what is  $M_2$ , so these you get from  $M_2$  and this you get from  $M_1$  and if you evaluate those expressions, you will get  $A_2/A_1$  is roughly 2.46.

If we use the compressible flow tables which are there in the appendix of the textbook, you will find that these values are tabulated,  $A/A^*$  as a function of Mach number. So, if you have a particular Mach number, you will get  $A/A^*$ , remember that it is just reproduction of the formula that we have derived in the class for  $\gamma = 1.4$  for here, so if it is for any other fluid you should have different tables for different fluids.

**(Refer Slide Time: 15:06)**

The table which is there in the appendix of your textbook is for air, so you may either use the table or you may use the formula to find out these expressions, okay. Let us work out a third problem, so it is given that this is the shape of a duct with the diameter at the inlet as 5 centimeter, diameter here that is  $d_2$  is 3 centimeter, the fluid is air with a stagnation temperature of 300 kelvin, upstream velocity  $u_1$  is given as 72 meter per second.

The pressure at the throat that is  $p_2$  is 124 kilopascal and assumes isentropic flow; from that find out what is  $p_1$ , what is  $M_2$  and what is the mass flow rate, okay. So, first of all we know  $u_1$ , so if we know what is the sonic speed at 1 then we may find out what is Mach number at 1, to find out what is the sonic speed at 1, what we should do; we should find out the temperature at 1 and to find the temperature at 1, we should use the energy equation.

So,  $T_0$  is  $- T + u^2 / 2 C_p$ , so from here you know what is  $T_0$  that is given, you know what is  $u_1$  that is given,  $C_p$  of air is known from that you can find out what is  $T_1$ , so  $T_1$  is 297.4 kelvin. So, once you know  $T_1$ , you know  $M_1$  that is  $u_1 / \text{square root of } \gamma R T_1$  and that turns out to be 0.208. Once you know  $M_1$ , you can find out  $A_1/A_1^*$ , it is a function of  $M_1$  only, okay.

So, when you find out this one from here,  $A_1$  is given;  $A_1$  is  $\pi d_1^2 / 4$ , this function of Mach number is known, so from here you can find out what is  $A_1^*$ . So, the value of  $A_1^*$  is 0.0006886 meter square if you calculate that is what you will find out. Now, what is  $A_2/A_2^*$ ?  $A_2/A_2^*$  is nothing but  $A_2/A_1^*$  remember,  $A^*$  remains same so long as it is the isentropic flow.

So, A star has already been calculated, this is A1 star is same as A star and A2 is  $\pi d^2 \text{ square}/4$ , so by putting these values, you will get these as 1.027 and this is a function of M2 and from this you can find out what is M2 by referring to the table of isentropic flows. So, M2 is; if you calculate this, this is 0.831. Once you know the Mach numbers basically you know everything because then you can use the expressions for  $P/P_0$ ,  $T/T_0$  like that.

**(Refer Slide Time: 19:57)**

Handwritten notes on a slide showing the calculation of mass flow rate and pressure ratios for isentropic flow. The notes include the following equations and values:

$$T_0 \rightarrow P_0$$

$$\text{from } M_1 \rightarrow \frac{P_0}{P_1} \rightarrow f_1(M_1)$$

$$\dot{m} = \rho_1 A_1 u_1 = \frac{P_1}{RT_1} A_1 u_1 = 0.313 \text{ kg/s}$$

$$P_1 = 189 \text{ kPa}$$

$$P_2 = 124 \text{ kPa}$$

So, you can calculate  $P_1/P_0$ , you know  $T_0$ , therefore you know  $P_0$ , from  $P_0$ , you may now calculate  $P_0/P_1$  as a function of Mach number at 1, so from that you can find out  $P_1$ . So, you can find out  $P_1$  not from this one but from Mach number at 1, so from so  $T_0$  will give you  $P_0$ , I am just outlining the procedure from the Mach number at 1, you have  $P_0/P_1$  as a function of Mach number from this, what is  $P_1$ .

So,  $P_1$  if you calculate it is 189 kilopascal and the mass flow rate, it is you can write  $\rho_1 A_1 u_1$  just as an example, you could also write as  $\rho_2 A_2 u_2$ ;  $\rho_1$  is  $P_1 / RT_1 * A_1 u_1$ , all these things you know, so you may substitute the values to get the mass flow rate which is 0.313 kg per second okay. So, we can see that how you may utilize the properties of isentropic flows to calculate different quantities, pressure, temperature, mass flow rate under different conditions.

Now, as we discussed in the previous class that it is not always true that one would have an isentropic flow or one may even think of an isentropic flow; isentropic flow is something which is not a reality in any way but real flows in certain cases may resemble very close to isentropic

flows but if you see that under certain cases even that approximation of isentropic flow will not work.

**(Refer Slide Time: 21:58)**

When it will not work, it will not work when there is an abrupt discontinuity in the flow, so how that abrupt discontinuity may be possible? Let us take an example, let us say that there is some aircraft which is moving with a very high speed, so when it is moving with a very high speed, it is say moving with a supersonic speed and therefore all the disturbances are confined within the Mach cone.

So, outside the Mach cone the disturbance is not felt, so let us say that you have sort of this as a bounding envelope within which the disturbance is there. Now, if you consider the streamlines which are there in the upstream, they are not still feeling the presence of these disturbances because the disturbance cannot propagate to all points. Now, suddenly when these come and encounter this point of or these locations of discontinuity then they will feel the presence of the disturbance.

And therefore, there will be an abrupt change in properties, so such abrupt change in properties will be possible here with a condition that on one side, it is supersonic flow and on another side what will happen, we will see; we are not predicting that it is either subsonic or supersonic or whatever but one important thing we can predict that there may be a sharp discontinuity, so that on one side, it is sort of the disturbance is failed because of the supersonic nature of the flow.

On another side the disturbance is not failed, so to say that is an extreme example but you may also have such discontinuities not that on one side disturbance is totally failed on another side the disturbance is not at all failed but there is a sharp discontinuity across that which means that there will be an abrupt change in Mach number across that. The question will be that; what is the length or what is the thickness over which this discontinuity occurs typically a few molecular mean free paths?

So, roughly like of the order of 0.1 micron like that so, it is for all macroscopic calculations, it is as if like a sharp front over which these discontinuities in the flow properties is going to be there, we will see that mathematically, we might initially have possibilities of several types of discontinuities but from the second law of thermodynamics, we will try to predict that some of these discontinuities are feasible and some of these discontinuities are not feasible.

But we have to first appreciate that there is a possibility of such discontinuity in a flow typically, in a supersonic flow we may visualize that why such a discontinuity might occur. The second thing is that when the discontinuity is occurring, what is the front over which the discontinuity is occurring? The front over which the discontinuity is occurring this type of discontinuity is known as a shock.

So, when you have the front over the discontinuity that is occurring that front may not be oriented in a direction normal to the direction of the flow but there are special cases, when the front of the discontinuity is oriented in a direction perpendicular to the direction of the flow and in such a case, it is known as a normal shock. If the front of the shock is oriented at an oblique angle with respect to the direction of the flow, then that is known as an oblique shock.

**(Refer Slide Time: 25:49)**

So, in the purview of this course, we have only normal shock, so we will be discussing only the special type of shock where the shock front is perpendicular to the direction of the flow. So, let us take up that case known as normal shock. So, when you have a normal shock, let us say that this is the shock front, so what we are having; we are having a discontinuity in properties across the shock front.

So, let us say on one side the pressure is  $P_1$ , the temperature is  $T_1$  maybe the velocity is  $u_1$ , the Mach number is  $M_1$ , another side  $P_2$ ,  $T_2$ ,  $u_2$ ,  $M_2$ , even you may write the density  $\rho_1$ ,  $\rho_2$  like that so there is a change in property. One important thing we should keep in mind that we also considered a wave type of motion; a weak wave type of motion where there was some discontinuity across the two ends on the front.

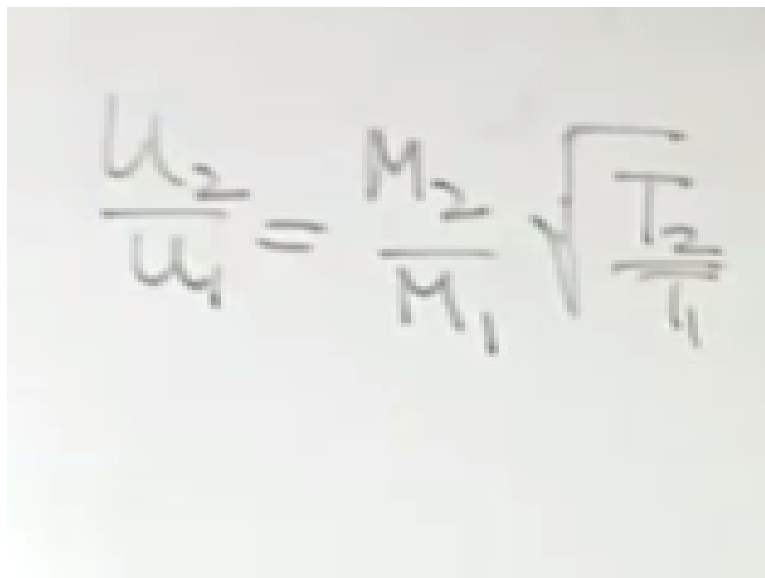

What is the difference between that and the shock wave? The big difference is there, the discontinuity was only infinitesimal that is if the pressure here was  $P$  maybe here was  $P + dP$  like that so that was a differential change or so to say a smooth change, here it is an abrupt change. So, difference between  $P_1$  and  $P_2$  is not differential, difference between  $M_1$  and  $M_2$  is not differential and that is why these are sharp discontinuities or jumped discontinuities.

So, when you have such jump discontinuities occurring, then these discontinuities occurring at a very rapid rate, so there is a rapid change in the flow properties and when there is such a rapid change, the change is taking place over a very thin region, so that we may consider it to be adiabatic because there is insufficient time to have opportunity of heat transfer during the process but because the process is very fast, it is no more reversible process.

Therefore, it may be approximated as an irreversible and adiabatic process, so if you have it as an irreversible process, you cannot apply isentropic flow conditions to relate  $M_1$ ,  $M_2$ ,  $u_1$ ,  $u_2$ ,  $T_1$ ,  $T_2$ ,  $P_1$ ,  $P_2$  like that and that is why we have to make a separate analysis for the shock. So, this is the motivation of having a separate analysis for the shock despite having the well-known property relationships for the isentropic flows.

Now, let us say that we want to apply our basic equations, so the basic equations are still valid, so you have; for example the continuity equation, remember these are one dimensional flows, so if  $A$  is the area of the shock front then you have  $\rho_1 A_1 u_1 = \rho_2 A_2 u_2$ ;  $A_1$  and  $A_2$  are the same and you may relate  $\rho_1$  with  $P_1$  and  $T_1$ , it is important to eliminate one of the variables out of  $P, T$  and  $\rho$  by using the equation of state.

**(Refer Slide Time: 29:31)**

$$\frac{u_2}{u_1} = \frac{M_2}{M_1} \sqrt{\frac{T_2}{T_1}}$$

So, you can write this as  $P_1 / RT_1 u_1 = P_2 / RT_2 u_2$ , so this one we will keep in mind, of course  $u_2/u_1$ , you may express in terms of the Mach number and the temperature, so you can also write  $u_2/u_1$  as  $M_2 / M_1$  square root of  $T_2 / T_1$  because  $u$  is  $M * C$ ;  $C$  is square root of  $\gamma RT$ . See, we are writing this with an understanding that in the upstream of the shock and in the downstream of the shock separately, we are using isentropic considerations that we have to keep in mind.

**(Refer Slide Time: 30:15)**

$$\rho_1 A_1 u_1 = \rho_2 A_2 u_2$$

$$(p_1 - p_2) A = \rho (u_2^2 - u_1^2)$$

$$\frac{\rho_1}{\rho_2} = \frac{p_1}{p_2}^{\frac{1}{\gamma}}$$

$$p_1 [1 + \gamma M_1^2] = p_2 [1 + \gamma M_2^2]$$

But in between the upstream and the downstream, the flow is not isentropic, so this is what we get from the continuity equation then maybe momentum equation; momentum equation, so the resultant force that acts on the control volume  $P_1 - P_2 \cdot A$  is  $\dot{M} \cdot u_2 - u_1$ ,  $\dot{M}$  is  $\rho \cdot A \cdot u$ , so in place of  $\dot{M}$ , you can write  $\rho_1 A u_1$  or  $\rho_2 A u_2$  either way and then if  $A$  gets cancelled from both sides, it is possible to write  $P_1 - P_2$  is  $= \rho_2 u_2^2 - \rho_1 u_1^2$  square okay.

Now, in place of  $\rho$ , you write  $P/RT$ , so  $P_2/RT_2$ , in place of  $u$  square, it is  $M^2 \cdot \gamma RT$ , right, so  $R \cdot T$  gets cancelled out, so this term becomes  $\gamma \cdot P_2 \cdot M_2^2$  square remain, the other term therefore will be  $P_1 M_1^2 \cdot \gamma$ , right. So, from here you can write  $P_1 \cdot [1 + \gamma M_1^2] = P_2 \cdot [1 + \gamma M_2^2]$ . So, from this we have an expression or relationship between  $P_1$  and  $P_2$ , which is solely expressed in terms of the Mach numbers at 1 and 2.

**(Refer Slide Time: 32:48)**

$$\text{Energy } C_p T_1 + \frac{u_1^2}{2} = C_p T_2 + \frac{u_2^2}{2}$$

$$C_p T_1 + \frac{M_1^2 \gamma R T_1}{2} = C_p T_2 + \frac{M_2^2 \gamma R T_2}{2}$$

$$T_1 \left[ \frac{1}{\gamma-1} + \frac{M_1^2}{2} \right] = T_2 \left[ \frac{1}{\gamma-1} + \frac{M_2^2}{2} \right] \quad (4)$$

So, we will keep this equation in mind, let us say this is equation number 1, this is equation number 2, this is equation number 3. The next important equation is the energy equation, so let us see that what we get out of the energy equation. Energy equation will give what?  $T_1 + C_p * T_1 + u_1^2 / 2 = C_p * T_2 + u_2^2 / 2$ . Remember, this is adiabatic and that is good enough this is first law of thermodynamics, we do not require any reversible or irreversible condition here.

So, you have  $C_p * T_1 +$  in case of  $u_1^2$  square, we will be using the expression of the Mach number that is  $u_1^2$  square is  $M_1^2 \gamma R T_1 / 2$ , okay, you can write  $C_p$  in terms of  $\gamma$  and  $R$ , so that is  $\gamma / (\gamma - 1) * R$ , right. So, this will become  $\gamma / (\gamma - 1) * R$ , this is  $\gamma / (\gamma - 1) * R$ , so  $\gamma * R$  will cancel, so you will have  $T_1 * 1 / (\gamma - 1) + M_1^2 / 2 = T_2 * 1 / (\gamma - 1) + M_2^2 / 2$ , okay.

So, let us be careful that there is no algebraic mistake because we require these calculations for some analysis subsequently. So, we are able to write  $T_1/T_2$  also in principle as a function of  $M_1$  and  $M_2$  just like what we could do for  $P_1/P_2$  and therefore,  $\rho_1/\rho_2$  also we will be able to do and  $u_1/u_2$  also in terms of  $M_1/M_2$  because  $T_2/T_1$  also is expressible in terms of  $M_1/M_2$ .

**(Refer Slide Time: 35:34)**

$$T_1 \left[ \frac{1}{\gamma-1} + \frac{M_1^2}{2} \right] = T_2 \left[ \frac{1}{\gamma-1} + \frac{M_2^2}{2} \right] \quad (4)$$

$$\textcircled{1} \rightarrow \frac{P_1}{P_2} \frac{u_1}{u_2} = \frac{T_1}{T_2}$$

$$\frac{P_1}{P_2} \frac{M_1}{M_2} \sqrt{\frac{T_1}{T_2}} = \sqrt{\frac{T_1}{T_2}}$$

$$\left( \frac{1+\gamma M_2^2}{1+\gamma M_1^2} \right) \frac{M_1}{M_2} = \frac{1}{\gamma-1} + \frac{M_2^2}{2}$$

$$\text{let } M_1^2 = x, M_2^2 = y$$

$$x(1+\gamma y)^2 \left( \frac{2}{\gamma-1} + x \right) = y(1+\gamma x)^2 \left( \frac{2}{\gamma-1} + y \right)$$

So, let us refer to the continuity equation that is equation number 1 form, so you have  $P_1/P_2 * u_1/u_2$  is  $= T_1/T_2$ , right and  $u_1/u_2$ , you can write in the next step from equation number 2;  $M_2/M_1$  square root of  $T_2$ ; sorry,  $M_1$ ; this is  $u_1/u_2$ , so  $M_1/M_2 * \text{square root of } T_2$ , then this is  $= T_1/T_2$ , so 1 square root of  $T_1/T_2$  gets cancelled, only 1 square root of  $T_1/T_2$  is there. Now, let us substitute from equation number 3 and equation number 4, where we have  $T_1/T_2$  and  $P_1/P_2$ .

So,  $P_1/P_2$  is  $1 + \gamma M_2^2 / 1 + \gamma M_1^2$  that  $* M_1/M_2$  is  $= \text{square root of } T_1/T_2$ , so 1/; okay, now we have got an explicit relationship between  $M_1$  and  $M_2$ , so to find out that what could be the possible relationship at the end, first of all we may square these expressions. So, if you square this expression, so this is the square;  $M_1^2/M_2^2$  and these square roots will go away.

Our objective is to solve  $M_2$  in terms of  $M_1$ , if you look into this equation carefully, you will see that  $M_1 = M_2$  is a trivial solution, right because when  $M_1 = M_2$ , each of the terms club will be  $= 1$ , so  $1 * 1 = 1$ , right. So,  $M_1 = M_2$  is a trivial solution but not a solution for the shock because for the shock there will be a discontinuity, so we have to look for the other solution which is different from  $M_1 = M_2$ .

Just to help in the algebra, let us say let  $M_1^2$  is  $= x$  and  $M_2^2$  is  $= y$  and let us just expand these terms, so we have  $1 + \gamma y$  whole square  $* x * 1/(\gamma-1)$ , let us write  $2/(\gamma-1) + x$  is  $= y * 1 +$ ; okay, so this term square  $* M_1^2$  is  $x$  into this term, which is

there in the denominator, so we have multiplied by 2 just for simplicity, so  $2/\gamma - 1 + x$ , okay.

So, just check whether this is correct or not because we will proceed again from this one. We will not do a brute force algebra but we will exploit the symmetry on the two sides, so first of all we will calculate the left hand side and we will write the right hand side just by exploiting the symmetry. See, right hand side is the replacement of the left hand side with  $x$  replaced by  $y$  and  $y$  replaced by  $x$ , okay.

**(Refer Slide Time: 40:32)**

$$x(1+\gamma y)^2 \left( \frac{2}{\gamma-1} + x \right) = y(1+\gamma x)^2$$

$$(x + \gamma^2 y^2 + 2\gamma xy) \left( \frac{2}{\gamma-1} + x \right)$$

$$\frac{2}{\gamma-1} x + \gamma^2 y^2 x + \frac{4\gamma}{\gamma-1} xy + x^2 + \gamma^2 x^2 y^2 + 2\gamma x^2 y$$

So, here you have  $x + \gamma^2 y^2 x + 2\gamma xy * 2/\gamma - 1 + x$ , this is the left hand side, doing one more step what you get;  $x^2$  okay, first  $x$ ;  $2/\gamma - 1 x + 2\gamma^2 y^2 x + 4\gamma xy$ , these are the first 3 terms and the next terms are just multipliers of  $x$ , so  $x^2 + \gamma^2 x^2 y^2 + 2\gamma x^2 y$ .

**(Refer Slide Time: 42:10)**

$$\left(\frac{2}{y-1} + y\right)$$

$$= \frac{2}{y-1}y + \frac{2y^2}{y-1}xy + \frac{4y}{y-1}xy + y^2 + 8x^2y^2 + 2xy^2x$$

We can straight away write that what will be in the right hand side, x will be replaced by y, so  $\frac{2}{\gamma - 1}y + 2\frac{\gamma^2}{\gamma - 1}x^2y + 4\frac{\gamma}{\gamma - 1}xy + y^2 + \gamma^2x^2y^2 + 2\gamma y^2x$ , so out of the total 6 terms that you get there are 2 terms which are symmetrical and same in the two sides and therefore they get cancelled.

(Refer Slide Time: 43:22)

$$\frac{2}{y-1}(x-y) - \frac{2y^2}{y-1}xy(x-y) + (x^2 - y^2) +$$

$$x \neq y$$

$$\frac{2}{y-1} - \frac{2y^2}{y-1}xy + x + y + 2xy = 0$$

$$y = \frac{x + \frac{2}{y-1}}{\frac{2y}{y-1}x - 1}$$

$$\textcircled{1} \rightarrow \frac{p_1}{p_2} \frac{u_1}{u_2} = \frac{T_1}{T_2}$$

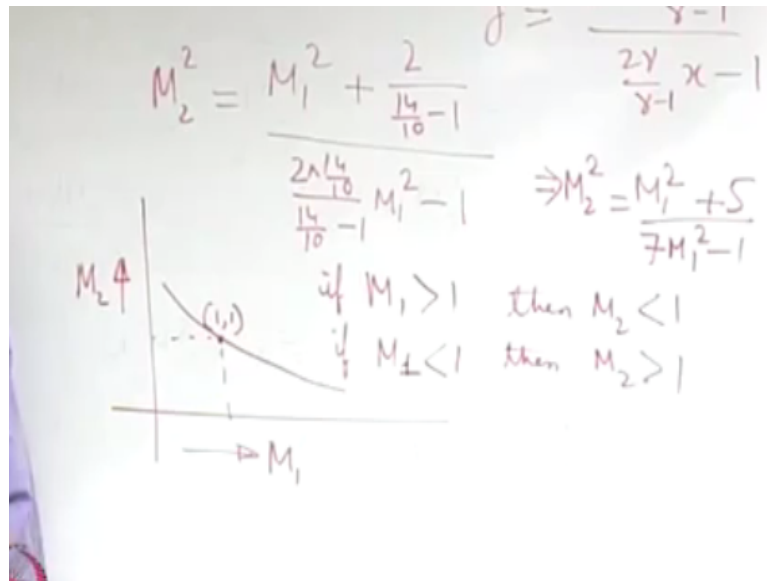

$$\frac{p_1}{p_2} \frac{M_1}{M_2} \sqrt{\frac{T_1}{T_2}} = \sqrt{\frac{T_1}{T_2}}$$

So, one is the term with xy, another is the term with x square y square and then you will automatically get x - y as a common thing because x = y is a trivial solution that we have seen. So, if you take x - y as common with  $\frac{2}{\gamma - 1}$  as the first term then from the next term,  $-\frac{2\gamma^2}{\gamma - 1}xy * x - y + x^2 - y^2 + 2\gamma xy * x - y = 0$ , okay. So, if you consider that x is  $\neq y$  then you have  $\frac{2}{\gamma - 1} - 2\frac{\gamma^2}{\gamma - 1}xy + x + y + 2\gamma xy = 0$ .

So, from here, it is possible to write  $y$ , explicitly as a function of  $x$ , right. So, if you write  $y$  explicitly as a function of  $x$ , let me give you the final expression that is a trivial war, so  $y$  will be  $= x / (x + 2/\gamma - 1/2\gamma)$  okay. So, when you get this expression, remember  $y$  is  $M_2$  square and  $x$  is  $M_1$  square. The special case that is of interest to us is the case of air.

(Refer Slide Time: 45:56)

So, air is  $\gamma = 1.4$  example, so for air let us write what is  $M_2$  square/  $M_1$  square, so  $M$  square is  $= M_1$  square  $+ 2/\gamma$  is  $14/10 - 1$ , we will just write it in a fractional form, so what will be  $M_2$  square in terms of  $M_1$  square? This will be  $4/10$ , so  $10 * 2$  in the numerator,  $20/4$  is 5, so this is  $M_1$  square/ 5;  $M_1$  square  $+ 5$  and this will be  $7 M_1$  square  $- 1$ . Now, let us try to make a plot of  $M_2$  as a function of  $M_1$  from this variation.

So, if you make a plot of  $M_2$  as a function of  $M_1$ , just as a sketch; one of the important observations is if you see again from this figure, from this expression when  $M_1$  is 1,  $M_2$  is 1, so 1, 1 is a point of this variation. So, if you say this has 1, 1, this is one point and the remaining thing if you make a plot, it will be a plot like this just schematically. So, from this what we can conclude is; if  $M_1 > 1$ , this is 1, then  $M_2$  is  $< 1$ .

And if  $M_2$  is; if  $M_1$  is  $< 1$  then  $M_2$  is  $> 1$ , till now whatever exercise we have done, this allows us with these 2 possibilities but we will see soon that both of these possibilities are not; out of these 2, one is not physically permissible because we have to consider the directionality of the

process, we have one process where the Mach number is going from  $> 1$  to  $< 1$ , another case going from  $< 1$  to  $> 1$ .

So, these 2 are 2 different directionalities of the process, out of these one of the directionalities will be possible, another directionality of the process will not be possible, so what is the direction in which the process will move or is permissible to move will be dictated by the second law of thermodynamics. So, we will now consider that what is the corresponding change in entropy during this process?

So, remember that when you have a change in entropy, you have a change in entropy of the system plus change in entropy of the surroundings, so here there is no heat transfer, so there is no change in entropy associated with the heat transfer with the surroundings, so you have change in entropy with the system that is just  $S_2 - S_1$ .

**(Refer Slide Time: 49:39)**

Handwritten notes on a slide showing the derivation of the Rayleigh flow function. The notes include the equation  $y = \frac{x + \frac{2}{y-1}}{\frac{2y}{y-1}x - 1}$ , the Mach number relation  $M_2^2 = \frac{M_1^2 + 5}{7M_1^2 - 1}$ , and the entropy change equation  $T ds = dh - v dp = dh - \frac{dp}{\rho}$ . It also shows the ideal gas law  $\frac{p}{\rho} = RT$  and the final expression for entropy change:  $s_2 - s_1 = C_p \ln \frac{T_2}{T_1} - R \ln \frac{p_2}{p_1}$ .

So, just to have elementary considerations on the change in entropy, the first law of thermodynamics in terms of a heat transfer; the heat transfer, remember the convention that we are having this is heat transfer to the system as positive, work done by the system as positive that is the sign convention that we have used,  $i$  is the internal energy this is actually the total energy that we should have return.

But we have neglected the changes in kinetic and potential energy in comparison to the internal energy that is why it is  $dh$  of internal energy. If we consider a process that is a quasi-static one or a very slow one and no other effect other than the pressure and the volume changes then this

becomes  $p dv$ , where  $v$  is the specific volume that is volume per unit mass and if we consider the process to be reversible, then we can write  $\delta q$  as  $T ds$ .

Once we have written this, it is  $T ds = di + p dv$  that is valid for any process, so long as we integrate this equation along a reversible path and calculate the change in property by following that path but once the property change is calculated, it becomes independent of the path because these are exact differentials or path independent expressions. So, you may express  $i$  in terms of  $h$  or express enthalpy in terms of internal energy;  $i + pv$ .

So, if you combine that what will follow is;  $T ds = dh - v dp$ , where  $v$  is the specific volume which is nothing but  $1/\text{density}$ . So, here in fluid mechanics, we usually refer to that density instead of the specific volume, so we will write  $1/\rho$ , we are using an ideal gas with constant  $C_p$   $C_v$  that is a perfect gas, so  $T ds = C_p dT - dp/\rho$ . So,  $ds = C_p dT/T - dp/(\rho T)$ ; so when you divide it by  $\rho T$ ; divided by  $T$ , it is  $\rho \cdot T$ , so you have to remember that  $p/\rho = RT$ .

So,  $\rho \cdot T$  is  $P/R$ , so  $-R dp/p$ , okay so you may integrate this expression and find out  $S_2 - S_1 = C_p \ln T_2/T_1 - R \ln p_2/p_1$ ,  $T_2/T_1$  and  $p_2/p_1$  we may write explicitly in terms of  $M_2$  and  $M_1$  in this case and that also solely in terms of  $M_1$  because  $M_2$  may be expressed solely as a function of  $M_1$ , so after doing all that the algebra is too complicated, we will not go into the algebra.

**(Refer Slide Time: 53:12)**

But we may see that what would be the  $S_2 - S_1$  as a function of  $M_1$  plot, in principle we understand that it is very, very much possible to get an expression  $S_2 - S_1$  solely as a function

of  $M_1$ , so if we make that plot, the plot will look something like this, it will be a plot like this. So, now if you look at this plot, you can clearly see that below  $M_1 = 1$ , you have  $S_2 - S_1 < 0$ , so this is giving rise to a total change in entropy as negative.

Remember the total change in entropy is  $S_2 - S_1 + \Delta S$  of the surroundings which is 0 because it is an adiabatic flow, so here  $S_2 - S_1$  is as good as  $S_{\text{net}}$ ;  $\Delta S_{\text{net}}$ . If there is a heat transfer with the surrounding, the  $\Delta S_{\text{net}}$  is  $S_2 - S_1 + \Delta S$  for the surroundings and we have to keep in mind that our requirement is not that  $S_2 - S_1$  should be  $> 0$  but  $\Delta S_{\text{net}}$  should be  $> 0$ .

In this case since, heat transfer = 0,  $\Delta S_{\text{net}}$  is same as  $S_2 - S_1$ , so from this what we can conclude is that this part is not a physically realistic part of the solution because it is giving rise to negative change in entropy of the system plus surroundings therefore, only permissible part of the solution is that; so out of the 2 cases that we have considered if  $M_1 > 1$  then  $M_2 < 1$  this is the permissible solution.

If  $M_1 < 1$  then whatever it is then  $M_2 > 1$  is fine but that is not a permissible direction of the process because it violates the second law of thermodynamics, so this is what we say that is not possible. So, from here we conclude that if we have a shock; upstream of the shock the flow has to be supersonic and there should be a change in property such that it has an abrupt change from supersonic to the subsonic state.

Why physically it should occur for a supersonic flow in the upstream and not a subsonic flow? If you see that if you have a supersonic flow, the disturbances are not able to propagate in all directions, so there is a limited zone over which is the zone of action within which the disturbance is propagated. Therefore, there is an accumulation of the disturbances because the disturbances are not able to propagate in all directions at a rapid rate.

So, this accumulation of disturbances gets released in the form of a shock with an abrupt discontinuity, if the disturbances were not accumulated then it would have not been possible to have such a shock with an abrupt discontinuity. So, the shock is like a release of accumulation of disturbances in supersonic flows, so with this understanding we now have an idea that when you have a shock, you have the change in properties; abrupt change in properties.

**(Refer Slide Time: 56:54)**

$$M_1, M_2, \frac{P_2}{P_1}, \frac{T_2}{T_1}, \frac{P_{02}}{P_{01}}, \frac{A_2^*}{A_1^*}$$

$M_2 \uparrow$

And if you look into the tables of the textbooks that you have, you will find that there are tables corresponding to the shock waves and there are different types of tables depending on whether you are dealing with a normal shock or an oblique shock, so here we are dealing with a normal shock. So, for a normal shock, you will see that the tables will have the following data; the tables will have  $M_1$ ,  $M_2$  then  $P_2/P_1$ ,  $T_2/T_1$ ,  $P_{02}/P_{01}$  like this you will have.

So,  $M_1$ ,  $M_2$ ,  $P_2/P_1$ ,  $T_2/T_1$  all these fundamentally may be calculated from these considerations and also may be  $A_2^*/A_1^*$ , all these may be fundamentally calculated from the expressions that we get. So, when you calculate this one important thing you have to keep in mind is that it is possible to express all those in terms of  $M_2$  and  $M_2$  in terms of  $M_1$ , there is a change in stagnation property across the shock.

So,  $P_0$  is the stagnation pressure which would have remained the same in an isentropic flow but if it is not isentropic, there will be a change in  $P_0$ , so there is a ratio  $P_{02}/P_{01}$ , which is  $\neq 1$ , so across the shock there is a change in stagnation properties because the shock; across the shock the flow is not isentropic, there is an abrupt discontinuity and because of that you have difference in  $A^*$  also.

So,  $A^*$  changes across the shock because  $A^*$  is an equivalent;  $A$  at which sonic condition is achieved by following an isentropic process, across the shock it is not isentropic, so in the downstream of the shock, it is a different isentropic condition and that is why you have difference in  $A^*$ . So, let us stop here with this lecture, we will continue again in the next lecture. Thank you.
