Performance Characteristics of Centrifugal Compressors Part II.

(Refer Slide Time: 0:41)

Good morning and welcome you all to this session of the course. Now we will try to solve some problems. Okay. Here it is. Now let us see a problem now. Here also I did a mistake, this will be not, this will be repetition of this, this will be M, sorry, this will be M we are writing, N by root over T1 T and this will be for T3 T by by T1 T, this I did a mistake earlier, this will be like this, the 2 curves. Okay.

(Refer Slide Time: 1:13)

A centrifugal compressor has an impeller tip speed of 360 m/s. Determine (i) absolute Mach number of flow leaving the radial vanes of the impeller and (ii) the mass flow rate. The following data are given:

Impeller Tip speed	360 m/s
Radial component of flow velocity at impeller exit	30 m/s
Slip factor	0.9
Flow area at impeller exit	0.1 m ²
Power input factor	1.0
Isentropic efficiency	0.9
Inlet stagnation temperature	300 K
Inlet stagnation pressure	100 kN/m ²
R (for air)	287 J/kgK
γ (for air)	1.4

Inlet stagnation temperature 100 kN/m²
 Inlet stagnation pressure 287 J/kgK
 R (for air) 1.4
 γ (for air) 1.4

$$Ma = \frac{V_2}{\sqrt{\gamma R T_2}}$$

$$V_2 = \sqrt{V_{f2}^2 + V_{w2}^2}$$

$$V_{w2} = \sigma U_2$$

$$V_2 = \sqrt{(30)^2 + (0.9 \times 360)^2}$$

$$= 325.38 \text{ m/s.}$$

$$T_2 = ?$$

$$T_{2t} = T_{3t}$$

$$C_p(T_{2t} - T_{1t}) = \psi \sigma U_2^2$$

Now let us solve problems. So we have discussed the principal of, the characteristic curves, the concept of surge, the surge line, the maximum efficiency line and the choking line. Now let us consider this problem. A centrifugal compressor has an impeller tip speed 360 metre per second, this is the impeller tip speed. Determine absolute Mach number of flow leaving the radial vanes of the impeller and the mass flow rate. The following data are given, so data are given.

So let us see, the Mach number of flow leaving the radial vanes, absolute Mach number, means based on absolute velocity. If we recall the vane, now let me recall the vane like this. Sorry, this is the vane. It is not, oh oh , this is the vane, this is the vane. Now if this is the

vane, then what is the diagram that the velocity diagram, let me better show the things which I earlier showed you. This is the thing, I think this will be better to show like this, you can make things like this. Can you see? Okay.

Please. Why I am writing that, I am not doing the radial one? Here one thing is important that slip factor is given 0.9. That means here, due to the slip, what happens, we have a, this is rotating in this direction, U_2 , so V_{R2} is not radial because there is a slip, so V_{W2} , this is V_{W2} , V_{W2} . And V_{W2} is less than U_2 . What is U_2 , U_2 is this one, this is U_2 . So this is the absolute velocity V_2 . And this velocity is V_{F2} . This is V_{F2} . So this is the diagram because there is a slip, so therefore this is the outlet triangle.

Now what I will do, I will write what has to be found out, then it has to be found out that Mach number based on absolute velocity at the outlet of the impeller. So therefore I have to find out Mach number V_2 by root over $\gamma R T_2$, okay. Now how to find out V_2 ? V_2 is the absolute velocity. Now we to his root over, this is V_{F2} , V_{F2}^2 + this is V_{W2} , V_{W2}^2 . Now V_{W2} is not U_2 , okay, this is U_2 , this is U_2 . So V_{W2} is σU_2 .

Okay, now U_2 is 360 metre per second, V_{F2} is given, flow area, power input factor, impeller tip speed, flow area, mass flow rate, so V_{F2} is not given, impeller tip speed is given, radial component of flow velocity is given, V_{F2} is 30 metre per second. You will see that V_{F2} is 30 metre per second so therefore you get V_2 is equal to $30^2 + 0.9^2 \times 360^2$. I will not do everything, calculations square. In this way you will get a value of V_2 equals to, what is the value of, let me tell you the value of V_2 here, the value of V_2 is 325, you can check, 325.38 metre per second.

Now to find out the Mach number, you require this static temperature, here in the formula, it is $\gamma R T_2$, T_2 is the static temperature at the outlet of the vane. Now how to find out T_2 ? Now our main objective is to find out T_2 . Let us 1st find out the total temperature T_{2T} , we know that T_{2T} here is equal to T_{3T} , that means outlet total temperature from the compressor at the outlet of the diffuser. And we know that $C_p (T_{2T} - T_{1T})$, that is the work done, that is equal to $\psi \sigma U_2^2$ divided this is okay.

So now here you see T_{1T} is given where because the inlet stagnation temperature, 300 K is given. ψ is given, power input factor is given, one, now slip is given 0.9, σ is given 0.9, ψ is given, U_2 is given 360 metre per second, T_{1T} is given, the inlet stagnation temperature is 300 K, so everything is given except T_{2T} from which we can find out T_{2T} equals to what? T_{2T}

becomes equal to, ultimately if you calculate T2 T will be 416 K. I am not writing every step because everything I know, power input factor is given in the problem, slip factor is given in the problem and T1 T is given the problem, U2 is given in the problem.

(Refer Slide Time: 7:10)

A centrifugal compressor has an impeller tip speed of 360 m/s. Determine (i) absolute Mach number of flow leaving the radial vanes of the impeller and (ii) the mass flow rate. The following data are given:

Impeller Tip speed	360 m/s
Radial component of flow velocity at impeller exit	30 m/s
Slip factor	0.9
Flow area at impeller exit	0.1 m ²
Power input factor	1.0
Isentropic efficiency	0.9
Inlet stagnation temperature	300 K
Inlet stagnation pressure	100 kN/m ²
R (for air)	287 J/kgK
γ (for air)	1.4

Velocity triangle diagram showing: V_2 , V_{f2} , U_2 , T_{2t} , V_{w2} , V_2 .

$$Ma_2 = \frac{V_2}{\sqrt{\gamma R T_2}}$$

$$V_2 = \sqrt{V_{f2}^2 + V_{w2}^2}$$

$$V_{w2} = \sigma U_2$$

$$V_2 = \sqrt{(30)^2 + (0.9 \times 360)^2}$$

$$= 325.38 \text{ m/s.}$$

$$T_{2t} = T_2 + \frac{V_2^2}{2c_p}$$

$$T_{2t} = T_2 + \frac{325.38^2}{2 \times 1005}$$

$$T_{2t} = 416 \text{ K}$$

$$T_2 = 363.33 \text{ K}$$

$$Ma_2 = 0.85$$

Again I will show you the problem that impeller speed 360 metre per second, radial component of flow velocity 30 metres, slip factor is 0.9, flow area at impeller exit 0.1 square, it is not now required. Power input factor is given, isentropic efficiency given, inlet stagnation temperature, inlet stagnation pressure, then R and gamma. So here what is required, power input factor which is given as 1, the slip factor which is given is 0.9, U2 is 360 metre per second and T1 T is 300 K, we get T2 T.

Now what happens, T_2 how to find out T_2 ? Now T_2 has to be found out from the concept of the stagnation temperature. What is that? $T_2 +$ the temperature, then the velocity equivalence, temperature equivalence of the dynamic head, that is V_2 square by 2 CP. That is the temperature equivalent of the kinetic energy, V_2 square by 2, that is total, this + this is the total temperature, from which we can find out T_2 is, T_2 T is now found out 416, now V_2 already we have found out 325.38 metre per second, the value of CP has to be found out from R and gamma.

Which you have read at school level that the specifically, the constant pressure is gamma by gamma -1 into R. So you know this is CP, so therefore from here you can find out the static temperature as 363.33K. Everything is known, so we know this static temperature. When we substitute this static temperature here, we get the Mach number equal to, the Mach number 2 for example, the 2 suffix I am using equals to 0.85 all right. Now the next is to find out the mass flow rate.

(Refer Slide Time: 9:01)

A centrifugal compressor has an impeller tip speed of 360 m/s. Determine (i) absolute Mach number of flow leaving the radial vanes of the impeller and (ii) the mass flow rate. The following data are given:

Impeller Tip speed	360 m/s
Radial component of flow velocity at impeller exit	30 m/s
Slip factor	0.9
Flow coefficient at impeller exit	0.1 m ²
Outlet factor	1.0
Isentropic efficiency	0.9
Inlet stagnation temperature	300 K
Inlet stagnation pressure	100 kN/m ²
Gas constant R	287 J/kgK
Gamma	1.4

Handwritten notes on the right side of the slide:

$$\dot{m} = \rho_2 A_2 V_2$$

$$A_2 = 0.1 \text{ m}^2$$

$$V_{f2} = 30 \text{ m/s}$$

$$\rho_2 = ? \quad \rho_2 = \frac{p_2}{R T_2}$$

$$\frac{p_{2t}}{p_{1t}} = \left[1 + \frac{\gamma_c (T_{2t} - T_{1t})}{T_{1t}} \right]^{\frac{\gamma}{\gamma-1}}$$

$$\eta_c = \frac{T_{2t} - T_{1t}}{T_{2t} - T_{1t}}$$

$$\frac{p_{2t}}{p_{1t}} = \left(\frac{T_{2t}}{T_{1t}} \right)^{\frac{\gamma}{\gamma-1}}$$

$$Ma_2 = \frac{V_2}{\sqrt{\gamma R T_2}}$$

$$V_2 = \sqrt{V_{f2}^2 + V_{w2}^2}$$

How to find out the mass flow rate? We will see the mass flow rate. Let me keep it here so that you can see. Now mass flow rate to find out, mass flow rate, let us write the mass flow rate. Mass flow rate is same throughout the machine. Let us write the mass flow rate based on the condition at the outlet of the diffuser ρ_2 , A_2 and the flow velocity. Now here A_2 is the flow area at the outlet of the impeller which is given you see here. Flow area is given, radial component of flow velocity, the mass flow rate, impeller speed, flow area at impeller exit, that means A_2 is already given, 0.1 metre square.

So what is not given, V_{F2} is given, the radial flow velocity coupled with the impeller exit is given, V_{F2} is given, V_{F2} is what, 30 metre per second. It is alright, 30 metre per second. What is not given, ρ_2 . So how to calculate ρ_2 ? Now ρ_2 is P_2 by $R T_2$. Now T_2 I know, the static temperature, already, T_2 already is calculated here, so I do not know P_2 , how to calculate P_2 ? Now before calculating P_2 , you have to calculate the stagnation pressure, then if you calculate the stagnation pressure, then you can calculate the static pressure.

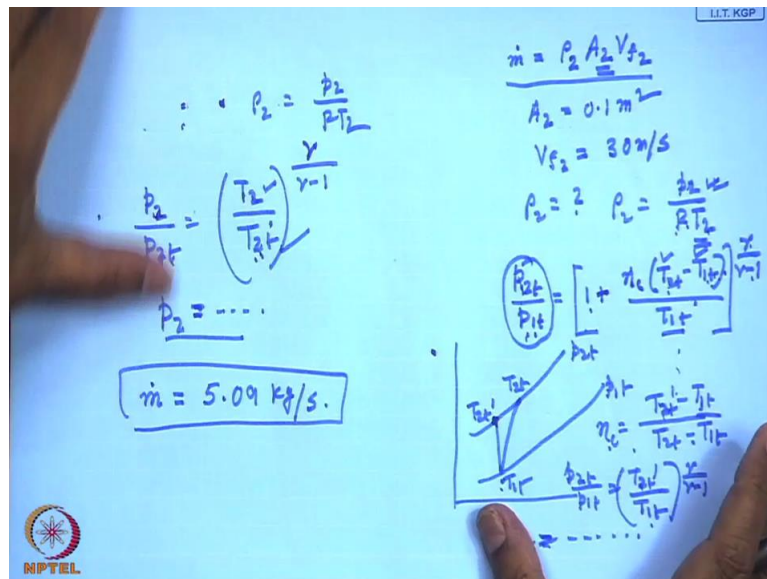

So how to calculate the stagnation pressure? So stagnation, stagnation pressure you can calculate P_2 by T_1 T from your this earlier formula $1 + \text{Eta C}$ into, you can calculate, write like that, $T_2 T - T_1 T$ divided by $T_1 T$ to the power, this has been told earlier, γ by $\gamma - 1$. So you remember this one that is the pressure, this comes from where, this comes from the isentropic relationship and then using the isentropic efficiency of the compressor.

Well, so using these relationship, we can find out, this relationship you remember, this was derived in the class, that means I find out this way that if these are the 2 pressure lines, then what happens. This $P_2 T$, $P_1 T$, then this is the thing, this is the $T_2 T$, $T_1 T$ and this is the $T_2 T$ dash. So $P_2 T$ by $P_1 T$ is $T_2 T$ dash by $T_1 T$ to the power γ by $\gamma - 1$. Now this $T_2 T$ dash by $T_1 T$ is found out by expressing this Eta C is $T_2 T$ dash -, I repeat again, this was done earlier, $- T_1 T$.

So therefore $T_2 T$ dash, that means $P_2 T$ by $P_1 T$ is $T_2 T$ dash by $T_1 T$ to the power, this is the isentropic relationship, $P T$ relationship. So this thing is taken from here, $T_2 T$ dash by $T_1 T$ Eta C into this $+1$. So Eta C into this by $T_1 T + 1$. So therefore we can write this, this is the thing done earlier. Now $T_2 T - T_1 T$ you know, already you know $T_2 T$, you already know $T_2 T$, $T_2 T$ is found out, $T_2 T$ is 416 K. You know $T_1 T$, $T_1 T$ is 300 K, given, Eta C is given in the problem, Eta C is what?

C is 0.9, so therefore $T_1 T$ is known, everything is known, you find out the $P_2 T$. Now after knowing the $P_2 T$, you have to know the P_2 because how, because ρ_2 is P_2 by $R T_2$. I rotate earlier, so you have to know the static pressure.

(Refer Slide Time: 13:11)

Now how to know the static pressure? By the concept of stagnation pressure, P_2 by $P_2 T$ is T_2 by T_2 to the power γ by... Wherefrom it comes? That means the static pressure is changed to stagnation pressure, that means when this is brought rest isentropically. That means this process of changing from P_2 to $P_2 T$ is obtained by bringing the fluid isentropically to this. That means therefore the gain in temperature $T_2 T$ from T_2 is made isentropically, so that the pressure ratio will be related to the isentropic relationship with the temperature ratio. This is the relationship between total stagnation pressure to the static pressure.

So therefore $T_2 T$ is known, therefore we get P_2 . So we can find out P_2 . You understand. So from here we find out $P_2 T$, $P_2 T$ is known, here we find out $P_2 T$, $P_2 T$ is found out here and here we find out P_2 , because $P_2 T$ is known, so finally P_2 is found. 1st we find out the ratio of the total pressure in terms of this, you know everything, $P_1 T$ you know, you know $P_2 T$. When you know $P_2 T$, you know P_2 from this equation. So P_2 is found out.

So when P_2 is found out, then you can find out ρ_2 from P_2 by $R T_2$ and you can find out the mass flow rate. So I am not doing things by putting the numerical values but I tell you the way, so this values you check, 5.09 KG because this will take more time to solve this by putting these values. So that is I am not doing, so if you put these values, you will get the results. I think there will be absolutely no problem. Now only substitute the numerical values and get the result and check the results with this.

(Refer Slide Time: 15:05)

The following data are suggested as a basis for the design of a single sided centrifugal compressor.

Power Input factor, $\psi = 1.04$	Air mass flow rate = 9 kg/s
Slip factor $\sigma = 0.9$	Inlet Stagnation Temperature = 295 K
Rotational Speed $N = 290 \text{ rev/s}$	Inlet Stagnation Pressure = 1.1 bar
Overall Impeller Diameter = 0.5 m	Isentropic efficiency $\eta_c = 0.78$
Eye tip diameter = 0.3 m	
Eye root diameter = 0.15 m	

(a) Pressure ratio of the compressor
 Power requirement
 Inlet angles of Impeller Vanes at root and tip
 radii of the eye

Now next another problem I will discuss before I leave you, so another problem is this one. Let us consider a problem like this. The following data are suggested as a basis for the design of a single sided centrifugal compressor. Single sided. Power input factor is 1.04, slip factor, 0.9, almost the similar problem which we discussed earlier, rotational speed is 290 revolutions per second, overall impeller diameter 0.5 metre, eye tip, eye root diameter. Air mass flow rate is given, in less stagnation temperature is given, in that stagnation pressure, isotropic efficiency.

(Refer Slide Time: 16:06)

$$\frac{p_{3t}}{p_{1t}} = \left[1 + \frac{\eta_c (T_{3t} - T_{1t})}{T_{1t}} \right]^{\frac{\gamma}{\gamma-1}}$$

$$C_p (T_{3t} - T_{1t}) = \psi \sigma \cdot u_2^2$$

$$T_{3t} - T_{1t} = 193 \text{ K}$$

$$P = \dot{m} C_p (T_{3t} - T_{1t}) = 1746 \text{ kW}$$

$u_2 = \pi \times 0.5 \times 290 = 455.5 \text{ m/s}$
 $C_p = 1.005 \text{ kJ/kg K}$

$\Rightarrow 4.23$

Now what is to be found out, determine pressure ratio of the compressor, power requirements, inlet tangles of impeller vanes at root and tip radii of the eye. Now let us find out the most simple thing, the pressure ratio. How to find out the pressure ratio? Now pressure issue to find out, what we have to do, let us again write the pressure ratio formula. If you write the pressure ratio, now I write $P_3 T$ by $P_1 T$ is equal to come in terms of this stagnation temperature rise, I think this you know, again and again I am writing. Just now I have discussed this, just now I have discussed this that the stagnation of total pressure ratio.

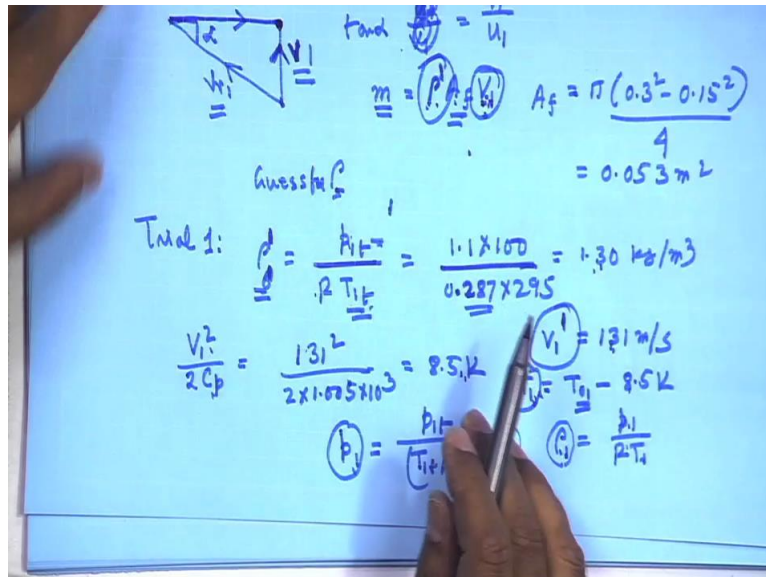

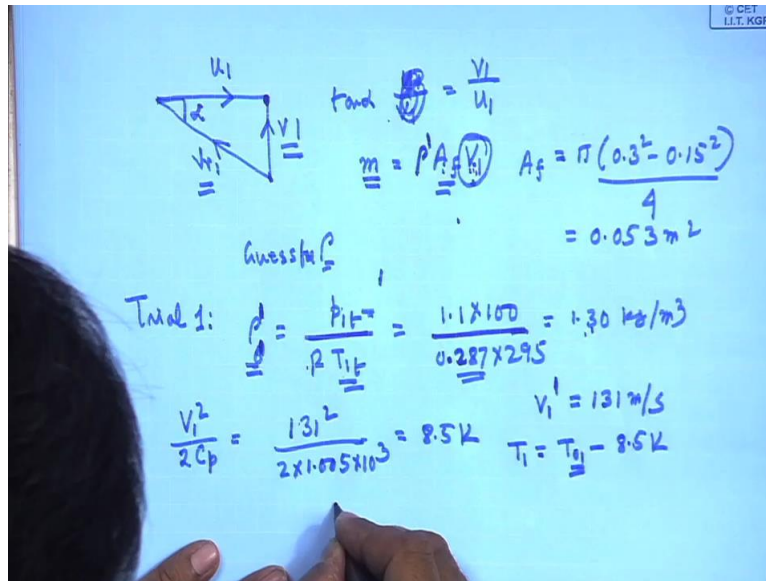

Here also the pressure ratio of the compressor, total pressure ratio $P_3 T$ by $P_1 T$ has to be found out. Now therefore what we require, we require $T_3 T - T_1 T$. How to find out $T_3 T - T_1 T$? Again the same formula we know, the work done to the fluid per unit mass or the energy added to the fluid per unit mass, it is psi power input factor, σU^2 , U^2 square. Now this thing can be found out provided psi, σ , U^2 square is given. What is given in the problem let me see.

This problem gives rotational speed at overall impeller diameter, 290 revolutions per second and overall impeller diameter 0.5. So U_2 is equal to pie into the overall diameter 0.5 into 290 is equal to the rotational speed, that means the tangential speed is 455.5 metre per second, that means U_2 is known. σ is given in the problem, if you see the slip factor is 0.9. σ is power input factor is 1.04, so if you put everything, you get the value of $T_3 T - T_1 T$ which becomes equal to $T_3 T - T_1 T$ is 193K.

Here the value of CP is not given in the problem. In the problem is the value of CP is not given in case you can use for air, the value of CP is 1.005 kilojoules, this is a specific speed, per KG K. So therefore you can use the value of CP and get $T_3 - T_1 T$. η_c is probably given in the, where is η_c , there is this isentropic efficiency, 0.78. So when you get the isentropic efficiency 0.78, the surface, $T_1 T$ is given, $T_1 T$ is the inlet stagnation temperature, inlet stagnation or total temperature, whatever you call, to 95K, so everything is known and this $T_3 T$ equals to, what is the value, equals to 4.23.

This you can check, so you can find out. So pressure ratio of the compressor is found. Power requirement, power requirement is mass flow rate into the CP, this work done per unit mass, T_1 , either this or this, both the things are same. So anyway you find out, the mass flow rate is given probably, otherwise power cannot be found out, air mass flow rate, 9 KG per second. So work per unit mass into mass flow rate is a power, you know everything, the power requirement is now 1746 kilowatts.

(Refer Slide Time: 19:41)

Alright, now the 2nd part is the inlet angles of impeller vanes at root and tip. Now at root and tip if you want to find out the impeller angles, then what will happen, let us find out root or tips anywhere at any representative section, it may be root, it may be tip. Okay, that means it may be root or it may be tip, that either it is, this is the root and this is the tip, so root and tip, axial flow velocity is constant, the normal flow velocity is constant, it is given there.

Okay, we will assume that, however, now what happens is that if we know the U_1 , the speed in V_1 , and V_{R1} , if this is this, α , just I wrote, I draw the right grams. So $\tan \alpha$ is U_1 by V_1 . So I have to know the flow velocity or the relative velocity, $\tan \alpha$ is oh, V_1 by, sorry, $\tan \alpha$ is V_1 by U_1 . So this is, if I know the, at root this velocity, then this will be

root, angle at the root, at the tip, it is angle at the tip. So root and tip, U_1 will be found out based on the root and tip diameter, that I know, because I know the rotational speed.

I know the rotational speed, I know the eye tip diameter, I know the eye root diameter, but here I know, I do not, I know neither V_1 , nor VR_1 . So how can I find out? So this type of problem is based on a trial. What trial, how to find out V_1 ? So V_1 is not known, so if you see from the mass flow rate basis, mass flow rate is given. $\rho A F V_1$. Okay, now $A F$ is given, how $A F$ is given, $A F$ is given because the eye tip diameter, eye root diameter is there. The one can find out $A F$ as $\pi (0.3^2 - 0.15^2) / 4$ and this becomes equal to 0.053 metres square.

So I know $A F$, so I have 2, these 2 I know, so what is that, I have to make a trial, guess for, guess for ρ and find out V_1 . How to guess for ρ ? This ρ , for example trial 1, this is the trial method. I guess ρ from the total pressure, $P_1 T R T_1 T$, at impeller eye I know $T_1 T$, I know $P_1 T$, based on this I find out in this value is given 1.1 bar into 100 by 0.287 into 295. This is the value given here, yes, 1.1 bar.

So this in terms of kilojoules, kilo, this Newton per metre square, converting this unit is there, that is why I have written 0.287 which is, it should be 10 to the power 5, then another 10 to the power 3 and then it will be 287, the characteristic gas constant, you see the consistent unit it is written and it becomes 1.30 KG per metre cube. Now if you know this ρ 1, 1st trial, this ρ 1, trial 1. You put that thing ρ 1 and if you know the mass flow rate is known, mass flow rate is already given in the problem, what is the mass flow rate? Mass flow rate is 9 KG per second, you get a value of V_1 .

Now when you get the value of V_1 , how to iterate, there should be a base on which you will iterate. When you get the value of V_1 , you can calculate the corresponding temperature, dynamic temperature by $V_1 C_P$. For example 1, this density you get, from this density you find out the V_1 . So with this density field find out the V_1 , then V_1 , for one trial will be 131 metre per second. So when you know the V_1 , then what you do, with this V_1 , you calculate gamma for 131 second V_1 square by 2 into 1.005 into 10 to the power 3, the corresponding temperature.

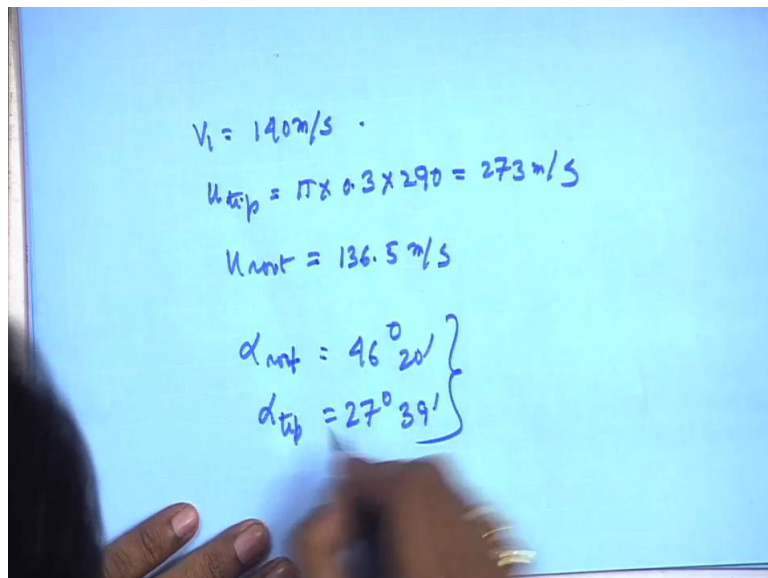

So if you know this temperature, you can calculate the static temperature, $T_0 1$ - this, 8.5 K. $T_0 1$ we know, so therefore we can find out this static temperature and at the same time, we can find out, this is a little labourious calculation I know but this is usually done in the

design. The static pressure as, as I told you the formula earlier, the static pressure and static, total pressure is related to the static temperature and total temperature to the isentropic relation. So I get P1.

When I get P1 and T1, I can find out rho 1 as P1 by R T1. That means by guessing a rho based on the stagnation condition I find out is V. When V is found out, I find out the dynamic equivalent temperature and with that temperature I can find out the static temperature in the static pressure by isentropic relation. When these 2 things are known, static pressure and temperature, then rho one is P1 by R T1. That means rho is getting connected. With this rho I find out again the corrected velocity.

So this way both rho and V, rho 1 and V1 1, V1 1 and rho 1 1, rho one is getting connected so that we get a converged value. When we have a converged value, then we get V1, when we get the V1, which is constant, the actual velocity of flow throughout the impeller passage is same. That means it is same as the, at the root and tip. Then what we will do, when we will use the peripheral speed at the root, then we will get the angle of the vane at the root and at the tip, then I will get the angle at the tip.

(Refer Slide Time: 26:04)

And if to do so, then you will get, I am giving you this value, the V1 converged value of V1 comes out to be 140 metre per second and U tip, you find out pie into as the value is given, you check the rotational speed into tip diameter, 273 metre per second and U root is equal to just half, the diameter is half metre per seconds and Alpha root, that by 10 Alpha, that formula, V1 by U, perpendicular by base, V1 by U, it becomes 46 degree and Alpha tip

becomes 27 degree. This is 20 minute in more from where I have taken, this is the value. So there is an iterative process by which you have to do. Okay. Thank you.
