Lecture – 16
Displacement Analysis:
Open Chain Robot – III

We will continue our discussions on the displacement analysis of robots. So, we have looked at 2 degree of freedom manipulators. Today we are going to look at a 3 degree of freedom parallel robot manipulator, open chain manipulator. So, this is the overview of today's lecture. So, the displacement analysis problem, forward and inverse kinematics of a 3R open chain planar manipulator.

(Refer Slide Time: 00:38)

(Refer Slide Time: 00:52)

Robot displacement analysis: plan

- Planar robots: **open chain**
- Planar robots: **closed chain**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, as we have discussed our plan, we are discussing planar robots with open chain, subsequently we will discuss planar robots with closed chain, configurations.

(Refer Slide Time: 01:10)

Displacement analysis: two problems

- Forward kinematics**: given actuator input, find output
- Inverse kinematics**: for specified output, find actuator input
- Inputs**: actuator displacement
- Output**: end-effector position and orientation

So, we have already defined this forward and inverse kinematics problem. So, there are two problems in displacement analysis. So, given the actuator input to find out the output motion of the end effector, and the inverse kinematics problem is for a specified output of the end effector; that means, specified position and possibly orientation of the end effector, we have to find out the actuator inputs. So, inputs of the actuator displacements and the output is the end effector position and orientation.

Open chain planar robots

- Two DOF kinematic chains: **2R, RP**
- Three DOF kinematic chains: **3R, RPR**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, now we are going to look at this 3 degree of freedom kinetic chain a 3R planar open chain manipulator. So, this is a schematic of a 3R planar open chain manipulator. And here I have written out for you the forward kinematics problem.

(Refer Slide Time: 02:06)

Planar 3R manipulator: forward kinematics

Diagram showing a 3R manipulator in a 2D Cartesian coordinate system (x, y). The base joint is a revolute joint (R) at the origin. The first link has length l_1 and makes an angle θ_1 with the x-axis. The second joint is a revolute joint (R) at the end of the first link. The second link has length l_2 and makes an angle θ_2 with the extension of the first link. The third joint is a revolute joint (R) at the end of the second link. The third link has length l_3 and makes an angle θ_3 with the extension of the second link. The end effector is at point (x_E, y_E) and its orientation is ϕ .

• Given: $(\theta_1, \theta_2, \theta_3)$ → Find: (x_E, y_E, ϕ)

So, given these angles theta 1, theta 2 and theta 3, we have to find out the location of the end effector. So, x_E and y_E . Since this is a 3 degree of freedom manipulator, so we can have 3 variables at our control. So, this x_E and y_E and this orientation angle phi. So, given theta 1, theta 2, theta 3, the forward kinematics problem is to find out x_E y_E plus

phi. So, x_E y_E these are the location, location of coordinates of the end effector and phi is the orientation of the orientation angle of the end effector.

(Refer Slide Time: 03:59)

So, here we have three Revolute pairs and we have to now find this relation. So, here is the schematic once again. So, what do you have to do? we need to, first we need to locate this coordinates of the end effector in terms of theta 1, theta 2 and theta 3. So, coordinates of the end effector. So, this is the x_E , I can write that this x_E is the summation of the projections of the 3 linked link lengths on the x axis that will give me x_E . So, therefore, x_E , I can write as projections of the link lengths, summation of the projections of the link lengths on the x axis. So, the projection of link length l_1 is $l_1 \cos \theta_1$, it is very easy to see; that is the projection of l_1 . So, $c \theta_1$ stands for cosine theta 1. Similarly the projection of l_2 and to add to this.

Now what is the projection? So, if I draw a line parallel to the x axis. So, cosine of this full angle now this full angle is, this is theta 1 remember. So, theta 1 and this is theta 2; so theta 1 plus theta 2. So, $l_2 \cos(\theta_1 + \theta_2)$. So, that gives me the projection of link length two, link length l_2 on the x axis; similarly the projection of link l_3 once again.

So, this is line parallel to the x axis; so, projection of l_3 on the x axis will be $l_3 \cos$ of this whole angle. Now this whole angle is composed of the following parts, this angle is same as this angle as you can see. So, this is theta 1 plus theta 2. So, therefore, the

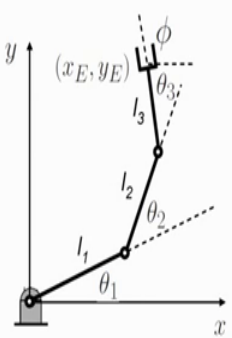

whole angle that l_3 makes with the x axis is $\theta_1 + \theta_2 + \theta_3$. So, therefore, I must add this projection as $l_3 \cos(\theta_1 + \theta_2 + \theta_3)$. So, that completes the x coordinate of the end effector.

Similarly, I can write the y coordinate as the projection of these link lengths on the y axis. So, to start with this is the projection of, this distance is the projection of l_1 on the y axis and this can be written as $l_1 \sin \theta_1$. So, therefore, the first term here is $l_1 \sin \theta_1$ plus.

Now the projection of l_2 on the y axis; so is nothing, but $l_2 \sin$ of this whole angle, and this whole angle is nothing, but $\theta_1 + \theta_2$. So, $l_2 \sin(\theta_1 + \theta_2)$. Similarly the projection of l_3 on the y axis is $l_3 \sin$ of this whole angle. now that whole angle is $\theta_1 + \theta_2 + \theta_3$ as we have noted. So, this becomes $l_3 \sin(\theta_1 + \theta_2 + \theta_3)$. So, that completes the y_E locational coordinate of the end effector, what remains is the orientation angle ϕ .

Now, you can very easily see that this, this full angle same as this angle ϕ . So, therefore, I can write ϕ as $\theta_1 + \theta_2 + \theta_3$. So, that completes the forward kinematics problem of this 3R planar open chain manipulator. So, I will show this to you formally.

(Refer Slide Time: 10:30)

•End-effector position coordinates

$$x_E = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2) + l_3 \cos(\theta_1 + \theta_2 + \theta_3)$$

$$y_E = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2) + l_3 \sin(\theta_1 + \theta_2 + \theta_3)$$

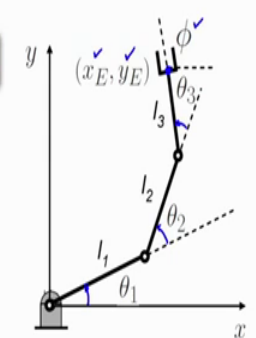

•End-effector orientation coordinate

$$\phi = \theta_1 + \theta_2 + \theta_3$$

So, this is the end effector positional coordinates x_E and y_E , and we have the orientation coordinate ϕ as $\theta_1 + \theta_2 + \theta_3$.

(Refer Slide Time: 10:55)

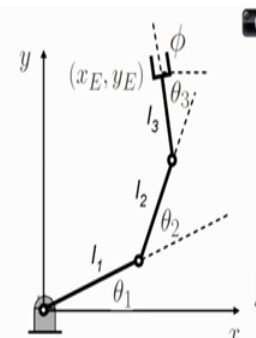

Planar 3R manipulator: inverse kinematics

• Given: (x_E, y_E, ϕ) Find: $(\theta_1, \theta_2, \theta_3)$

Now, the inverse kinematics problem; once again we have these angles θ_1 , θ_2 , θ_3 , which are now unknown, but what is known, is the location of the end effector; that means, x_E and y_E and the orientation of the end effector ϕ . So, these are the three quantities which are specified, and what we have to find out are these joint angles θ_1 , θ_2 and θ_3 . So, we will start with the forward kinematics expressions.

(Refer Slide Time: 11:54)

$$\begin{aligned} \checkmark x_E &= l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2) + l_3 \cos(\theta_1 + \theta_2 + \theta_3) \\ \checkmark y_E &= l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2) + l_3 \sin(\theta_1 + \theta_2 + \theta_3) \\ \checkmark \phi &= \theta_1 + \theta_2 + \theta_3 \end{aligned}$$

$$\begin{aligned} X &= x_E - l_3 c\phi = l_1 c\theta_1 + l_2 c(\theta_1 + \theta_2) \\ Y &= y_E - l_3 s\phi = l_1 s\theta_1 + l_2 s(\theta_1 + \theta_2) \end{aligned}$$

$$\begin{aligned} (X - l_1 c\theta_1)^2 + (Y - l_1 s\theta_1)^2 &= l_2^2 \\ X^2 + Y^2 + l_1^2 - 2l_1 X c\theta_1 - 2l_1 Y s\theta_1 &= l_2^2 \\ Y s\theta_1 + X c\theta_1 &= \frac{X^2 + Y^2 + l_1^2 - l_2^2}{2l_1} \\ A s\theta_1 + B c\theta_1 &= C \end{aligned}$$

So, the relation between x_E , y_E , ϕ and θ_1 , θ_2 , θ_3 . Then we note that you see this ϕ , this appears here and here in the locational coordinates of the end effector. So, therefore, I can replace these by ϕ which is specified. So, remember these quantities are specified. So, ϕ is known to me. Now once I substitute this θ_1 plus θ_2 plus θ_3 by ϕ , this term the third term is completely known to me. So, I can bring it to the left hand side and write. So, from the first equation and similarly from the second equation.

Now once I have these two equations, the left hand side remember is completely known to me, I call them X capital X and capital Y . So, capital X and capital Y are completely known, because x_E and ϕ are known to me. So, the problem now boils down to finding out θ_1 and θ_2 given capital X and capital Y . So, the simplest approach would be, to look at this x minus $l_1 \cos \theta_1$ whole square plus y minus $l_1 \sin \theta_1$ whole square. So, I have taken this term to the left, this term to the left the two equations squared them up and added them.

So, I get on the right hand side l_2^2 square. So, when I open this up, I get x^2 plus y^2 plus l_1^2 square minus $2 l_1 x \cos \theta_1$ minus $2 l_1 y \sin \theta_1$ is equal to l_2^2 square. So, I can now manipulate this and rewrite in this form by $\sin \theta_1$ plus $x \cos \theta_1$ is equal to x^2 plus y^2 plus l_1^2 squared minus l_2^2 square divided by $2 l_1$. So, I have re expressed this equation in this form. So, this form again is familiar $A \sin \theta_1$ plus $B \cos \theta_1$ equal to C . So, you can find the correspondence A is y , B is x and C is this, an expression on the right hand side.

So, let us look at these steps formally. So, I had the scab definitions of capital X and capital Y .

(Refer Slide Time: 17:37)

$x_E = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2) + l_3 \cos(\theta_1 + \theta_2 + \theta_3)$
 $y_E = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2) + l_3 \sin(\theta_1 + \theta_2 + \theta_3)$
 $\phi = \theta_1 + \theta_2 + \theta_3$
 $X = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2)$
 $Y = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2)$
 where
 $X = x_E - l_3 \cos \phi, \quad Y = y_E - l_3 \sin \phi$

(Refer Slide Time: 17:52)

$X = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2)$
 $Y = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2)$
 where
 $X = x_E - l_3 \cos \phi, \quad Y = y_E - l_3 \sin \phi$
 $(X - l_1 \cos \theta_1)^2 + (Y - l_1 \sin \theta_1)^2 = l_2^2$
 $\Rightarrow A \sin \theta_1 + B \cos \theta_1 = C$
 where
 $A = Y, \quad B = X, \quad C = \frac{X^2 + Y^2 + l_1^2 - l_2^2}{2l_1}$

Now these capital X capital Y in terms of theta 1 and theta 2. So, I took these terms on the left hand side squared them added and express this, which can be reframed in this form A sin theta 1 plus B cosine theta 1 is equal to C, where this A B and C we have seen how to derive. So, we know A B and C, because this X and Y are known to us; xE phi y e phi. So, these are all known to us; so capital X capital Y unknown. Therefore, A and B unknown. So, we are left with the only unknown theta 1 in this equation which we can solve.

(Refer Slide Time: 12:50)

$$X = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2)$$

$$Y = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2)$$
 where

$$X = x_E - l_3 \cos \phi, \quad Y = y_E - l_3 \sin \phi$$

$$(X - l_1 \cos \theta_1)^2 + (Y - l_1 \sin \theta_1)^2 = l_2^2$$

$$\Rightarrow A \sin \theta_1 + B \cos \theta_1 = C$$
 where

$$A = Y, \quad B = X, \quad C = \frac{X^2 + Y^2 + l_1^2 - l_2^2}{2l_1}$$

$$\tan(\theta_1 + \theta_2) = \frac{Y - l_1 \sin \theta_1}{X - l_1 \cos \theta_1}$$

So, that will give us the solution of theta 1. What about theta 2? So, theta 2, you can see that if I take these terms to the left hand side, and take the ratio of the second equation with the first, then I have tangent of theta 1 plus theta 2 is equal to y minus l 1 sin theta 1 by x minus l 1 cosine theta 1.

So, I have taken these terms to the left hand side and taken the ratio the second equation with the first and I have this. Now from here I will solve first solve for theta 1, then substitute this theta 1, solution of theta 1 into this and solve for theta 2. So, we are going to look at this step by step. So, first we are going to look at this equation. So, solution of A sin theta 1 plus B cosine theta 1 equal to C.

(Refer Slide Time: 21:19)

Solution of $A \sin \theta_1 + B \cos \theta_1 = C$

Let $x = \tan \frac{\theta_1}{2}$. Then

$$\sin \theta_1 = \frac{2x}{1+x^2} \quad \cos \theta_1 = \frac{1-x^2}{1+x^2}$$

Substituting in the equation yields

$$A \left(\frac{2x}{1+x^2} \right) + B \left(\frac{1-x^2}{1+x^2} \right) = C$$
$$\Rightarrow (B+C)x^2 - 2Ax + (C-B) = 0$$

Once again we make this definition, so that we express sin theta 1 and cosine theta 1 in this form in terms of x. These expressions when substituted into the master equation results in this quadratic equation in x, which we know how to solve.

(Refer Slide Time: 21:57)

$$(B+C)x^2 - 2Ax + (C-B) = 0$$

Solutions are

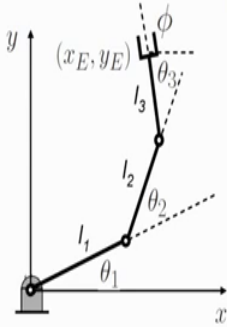

$$x = \tan \frac{\theta_1}{2} = \frac{A \pm \sqrt{A^2 + B^2 - C^2}}{B+C}$$

where

$$A = Y, \quad B = X, \quad C = \frac{X^2 + Y^2 + l_1^2 - l_2^2}{2l_1}$$

So, the solutions are given by this expression and x is tan theta 1 by 2. So, I know how to find out theta 1. Here A B and C are completely known. So, we will know x and hence tan theta 1, and finally, we have the solution of theta 1.

(Refer Slide Time: 22:30)

$$X = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2)$$

$$Y = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2)$$

where

$$X = x_E - l_3 \cos \phi, \quad Y = y_E - l_3 \sin \phi$$

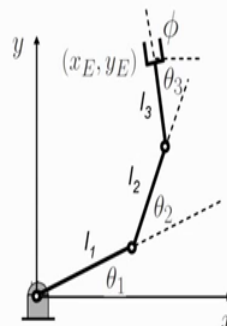

$$\tan(\theta_1 + \theta_2) = \frac{Y - l_1 \sin \theta_1}{X - l_1 \cos \theta_1}$$

$$\theta_3 = \phi - (\theta_1 + \theta_2)$$

Once we have the solution of theta 1 as we have discussed we form this expression. So, theta 1 is completely solved there are two solutions. So, therefore, I know theta 1. So, there are three places we need to substitute, and take the tangent inverse and get theta 2. Once I solve for theta 2, so I have theta 1 and theta 2 then I can solve for theta 3, because phi is known. So, that will complete the solution. and once again when you take tangent inverse here or in the previous step, we must use the atan 2 function.

(Refer Slide Time: 23:39)

Planar 3R manipulator: inverse kinematics

$$\theta_{11} = 2 \tan^{-1} \left[\frac{A - \sqrt{A^2 + B^2 - C^2}}{B + C} \right]$$

$$\theta_{12} = 2 \tan^{-1} \left[\frac{A + \sqrt{A^2 + B^2 - C^2}}{B + C} \right]$$

$$\tan(\theta_1 + \theta_2) = \frac{Y - l_1 \sin \theta_1}{X - l_1 \cos \theta_1}$$

$$\theta_3 = \phi - (\theta_1 + \theta_2)$$

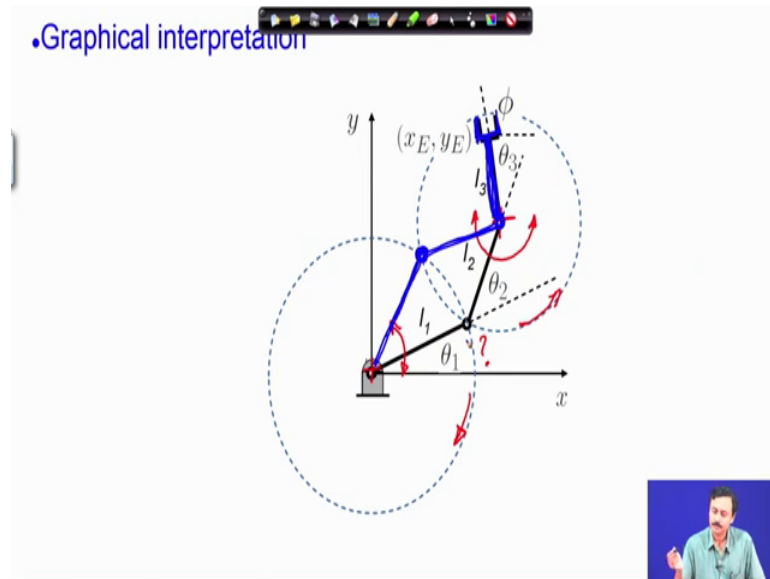

•Use atan2(y,x) function for correct quadrant

So, here is the complete solution in one go. So, we have these two solutions of theta 1, correspondingly we will find the solution of theta 2 from here and finally, theta 3. So, once again we use this atan two function, when we solve these things on the computer.

So, let us now understand the solution graphically.

(Refer Slide Time: 24:17)

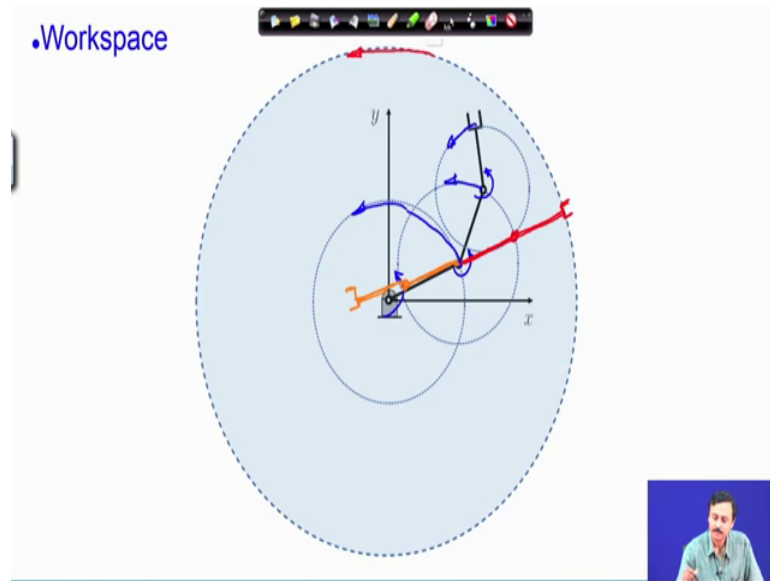

Here remember that x_E , y_E and ϕ these are specified. Once these three things are specified this link gets completely fixed, this gets completely fixed, because one point is fixed and the angle is fixed. So, this link is fixed completely. Therefore, this point is completely fixed. This revolute joint is completely fixed. What is not known is theta 1 and theta 2.

So, therefore, this is fixed, I can then rotate link 1 2 about this fixed point, and similarly link 1 1 can be rotated about this fixed point to find out where this hinge lies. So, this is the circle on which this hinge on link 2 moves, and this is this circle, this is the circle on which the hinge on link one moves. Therefore, the intersection points are the possible solutions. So, one solution is given in this black configuration.

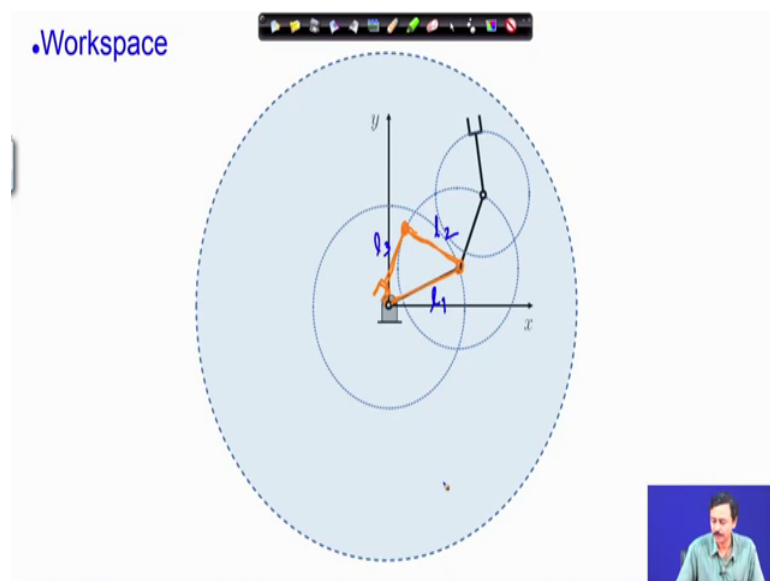

Let me draw the other configuration, other possible solutions in blue, so this. So, here is the revolute pair the hinge, and in the blue configuration also this link remains fixed, this is fixed. So, one is the black configuration the other is the blue configuration. These are the two solutions of the inverse kinematics problem.

(Refer Slide Time: 27:36)

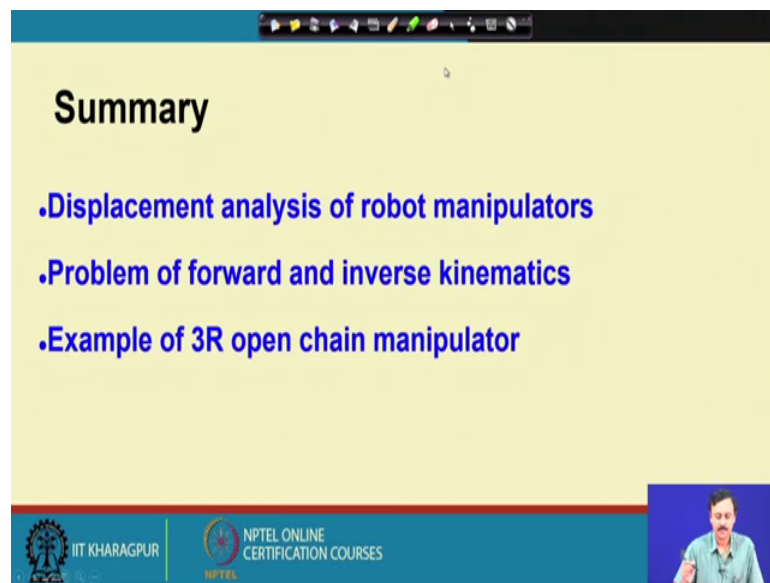

Next, we look at the workspace. If all the revolute pairs can rotate completely then we find that this revolute pair can go on this circle, this revolute pair can move on this circle and the end effector can rotate. So, these are the three Revolute pairs. So, the farthest reach is when, the manipulator is completely extended like this; that is the farthest reach. And by rotating this completely I can generate the boundary of the reach of the manipulator. On the inward side this can be folded, I can reach any point like this, I can reach points like this.

(Refer Slide Time: 29:38)

So, I can cover the complete space within the outer circle. So, I can reach any point in this region; so, for a 3R manipulator all points can be reached. So, that of course, will depend on these link lengths. So, these link lengths l_1, l_2, l_3 , the way I have drawn you can reach, but if l_2 and l_3 are short, then there might be some regions that are left out. So, that is the workspace for the 3R manipulator. There is another restriction that is on the joint angles, if they have limits then also the workspace gets restricted or reduced.

(Refer Slide Time: 31:04)

The image shows a presentation slide with a yellow background and a blue header. The title 'Summary' is in bold black text. Below it, three bullet points are listed in blue text: '.Displacement analysis of robot manipulators', '.Problem of forward and inverse kinematics', and '.Example of 3R open chain manipulator'. At the bottom of the slide, there is a blue footer containing the IIT Kharagpur logo and the text 'NPTEL ONLINE CERTIFICATION COURSES'. A small video inset in the bottom right corner shows a man in a light blue shirt speaking.

So, here is a summary. So, we have looked at the 3R open chain manipulator, looked at its forward and inverse kinematics, and we have discussed the geometric interpretation of the solutions of the inverse kinematics problem.

So, with that I will close this lecture.
