Lecture – 28
Velocity Analysis: Analytical Approach – III

Let us continue our discussion on velocity analysis problem using the analytical approach. We are going to look at another example of 3R1P chain of type 2 in this lecture.

(Refer Slide Time: 00:33)

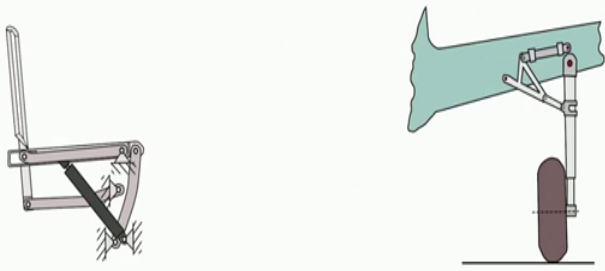

So, I will give you the overview of this lecture we are going to look at this example of chain of type 2 and we are also going to see briefly. How in more complicated chains these ideas can be extended very, very easily? Of course, the calculations might be little more involved, but then these ideas that we are discussing of velocity analysis can easily be applied to more complicated chains.

(Refer Slide Time: 01:10)

Velocity analysis

- Mechanism transforms actuator velocity input(s) to velocity of output link
- Velocity analysis: to find velocity input-output relation

So, the velocity analysis problem has been defined as the as finding out the input output velocity relation; that means, from the actuator to the output.

(Refer Slide Time: 01:23)

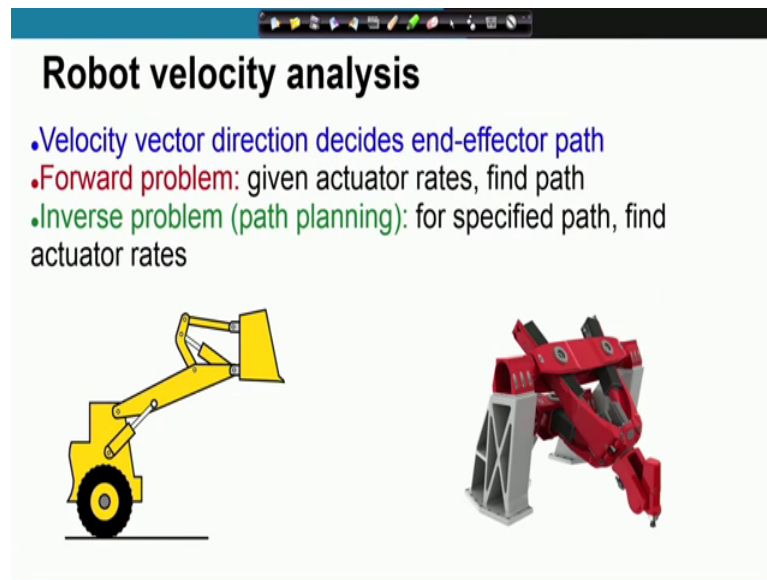

Constrained mechanism velocity analysis

- Forward problem: given actuator rates, find output velocity
- Inverse problem: for specified output velocity, find actuator rates

We have these problems for the constraint mechanisms.

(Refer Slide Time: 01:29)

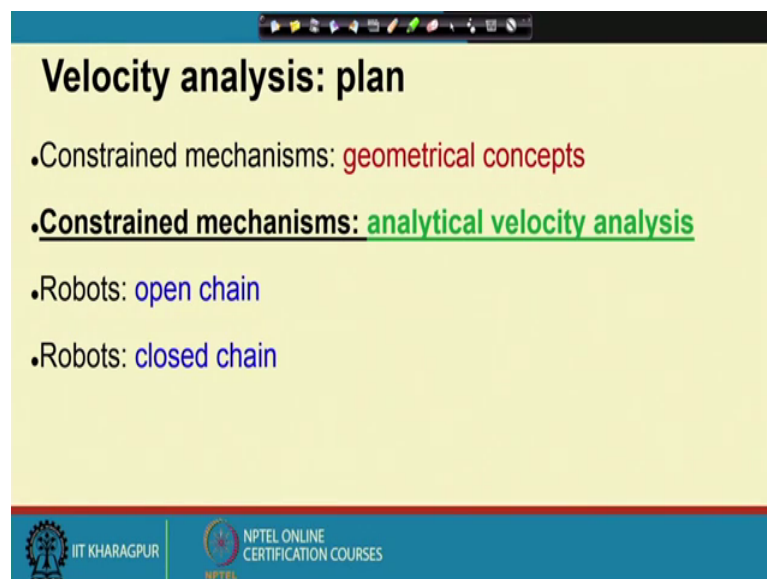

Robot velocity analysis

- Velocity vector direction decides end-effector path
- Forward problem: given actuator rates, find path
- Inverse problem (path planning): for specified path, find actuator rates

The slide features two illustrations: on the left, a yellow excavator with its arm raised; on the right, a red humanoid robot with its arms extended.

For robots, in which the path planning problem or path generation problem is of importance and which are intimately dependent on the velocity analysis problem for robots.

(Refer Slide Time: 01:45)

Velocity analysis: plan

- Constrained mechanisms: geometrical concepts
- Constrained mechanisms: analytical velocity analysis
- Robots: open chain
- Robots: closed chain

The slide includes logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES at the bottom.

Which we are going to discuss, we will continue with the analytical velocity analysis approach for constraint mechanisms.

(Refer Slide Time: 01:52)

Constrained mechanisms: velocity analysis

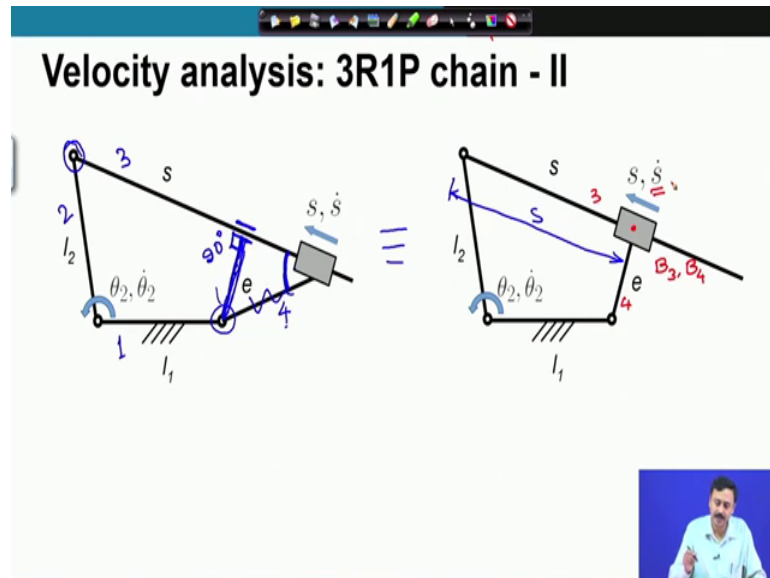

- Kinematic chains: 4R, 3R1P
- Displacement analysis completed
- Velocity analysis: Analytical method

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And we are going to look at the chain, we will consider that this displacement analysis is completed which means that we know the configuration of the mechanism. As you know in constraint mechanisms specifying one of the input one input will specify the configuration of the complete mechanism so, I can find out all other angles. Am angles and of course, the throw of the prismatic pair. So, here in the we have a prismatic pair. So, we can calculate everything given an input.

So, we are now going to discuss the velocity analysis problem, using the analytical method.

(Refer Slide Time: 02:41)

Now, in the chain of type 2 we have a prismatic pair which is changing the direction of the sliding as you can see here. As we have discussed before, you can see that this angle is going to remain fixed. When the prismatic pair expands or contracts so, to number the links the ground is 1, this is 2, this is 3, this is 4.

So, between lengths 3 and 4 we have the prismatic pair and this angle between lengths 3 and 4 is going to remain fixed. So, therefore, I can consider that this is same as having a prismatic pair like this. This is going to simplify my expressions and the analysis. So, this is e the offset. So, offset is measured perpendicular to the direction of sliding. So, this is 90 degree, this angle is 90 degree. E is measured perpendicular to the direction of sliding between the 2 revolute pairs at the end of the links containing the prismatic pair. So, So, 3 and 4 are connected by the prismatic pair and these 2 revolute pairs are at the ends of links 4 and links 3 and link 3 so, this perpendicular distance is the offset.

So, therefore, rather than having this I can join these 2 with at 90 degree and hence obtain a chain like this, which is equivalent these 2 are equivalent. Here, the distance S so, this is the throw of the actuator. We will consider this to be the throw of the actuator. So, 1 more important point here S is this length and I start is the velocity of a point belonging to link 3. Suppose we have a point coincident point belonging to link 3 called p_3 and another point at the same location which means B_3 and B_4 a coincident. So, B_3

belongs to link 3 and B4 belongs to link 4. So, the relative velocity between B3 and B4 is $s \dot{}$. So, that is the expansion rate of the prismatic actuator.

(Refer Slide Time: 06:30)

Velocity analysis: 3R1P chain - II

- Configuration (θ_2, s) : displacement analysis
- To determine relation between $\dot{\theta}_2$ and \dot{s}

So, the configuration of the mechanism is known to us, which means θ_2 and also this angle θ_3 of course, these are all known to us θ_2 , θ_3 these are all known to us from displacement analysis. We have to find out the relation between $\dot{\theta}_2$ and \dot{s} . So, we have to find out this relation.

(Refer Slide Time: 07:15)

$$PQ^2 = s^2 + e^2$$

From $\triangle PQR$,

$$PQ^2 = l_1^2 + l_2^2 - 2l_1l_2 \cos \theta_2$$

$$\Rightarrow \cos \theta_2 = \frac{l_1^2 + l_2^2 - s^2 - e^2}{2l_1l_2}$$

• Two solutions of θ_2

Now, we have looked at the displacement analysis problem for this kinematic chain.

So, we are going to follow through PQ which is this distance. This distance can be related to S and e the offset by this relation. Because, this angle is 90 degree. Therefore, I can write PQ square is s square plus c square. Now from triangle PQR this PQ square using the cosine rule I can write in terms of the angle theta 2. So, this angle is theta 2. So, I can relate PQ also from the other side using theta 2 and this is what we have. So, I put this PQ square expression of PQ square in this to finally, obtain this relation.

Now, this equation this is the displacement relation relates theta 2 and S. Now, there are 2 solutions of theta 2 as you know you can find them, so these are the 2 configurations corresponding to a specified value of S or a specified value of theta 2. There are 2 solutions, so this is what we have this displacement relation. If I differentiate this with respect to time as we have been doing.

(Refer Slide Time: 09:11)

$$\frac{d}{dt} \left[\cos \theta_2 = \frac{l_1^2 + l_2^2 - s^2 - e^2}{2l_1 l_2} \right]$$

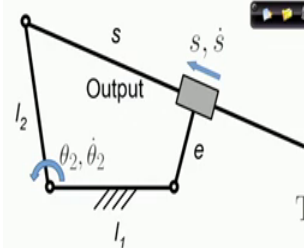

$$-\dot{\theta}_2 s \sin \theta_2 = \frac{1}{2l_1 l_2} [-2s \dot{s}]$$

$$\dot{\theta}_2 = \frac{s}{l_1 l_2 s \sin \theta_2} \dot{s}$$

So, this is the displacement relation, so what do we have? Minus of theta 2 dot into sine theta 2 is equal to 1 by twice of l1 l2 times. Now these are constants l1 is constant l2 is constant. The only thing variable is S, e is a constant. So, this is as simple as that. So, therefore, I can relate, let us say theta 2 dot as like this.

So, theta 2 dot is S divided by l1 l2 sine theta 2 into S dot. And I can invert also I can express s dot in terms of theta 2 dot, so let me formalize this.

(Refer Slide Time: 11:03)

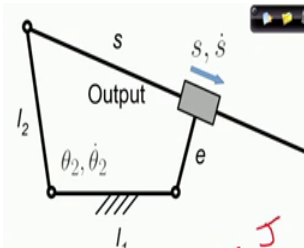

$$\cos \theta_2 = \frac{l_1^2 + l_2^2 - s^2 - e^2}{2l_1 l_2}$$

Time differentiating both sides

$$\dot{\theta}_2 = \left[\frac{s}{l_1 l_2 \sin \theta_2} \right] \dot{s}$$

So, we have this expression which we just now derived relating S dot and theta 2 dot.

(Refer Slide Time: 11:16)

$$\dot{\theta}_2 = \left[\frac{s}{l_1 l_2 \sin \theta_2} \right] \dot{s} \Rightarrow \dot{\theta}_2 = J \dot{s}$$

$$\dot{s} = \left[\frac{l_1 l_2 \sin \theta_2}{s} \right] \dot{\theta}_2 \Rightarrow \dot{s} = J^{-1} \dot{\theta}_2$$

where J is known as the Jacobian (scalar).

So, here I am defining this as the Jacobean which is again a scalar. So, Jacobean is in terms of S and theta 2. And if you invert the relation then you get it in terms of Jacobean inverse, which is 1 over j. It is a scalar so, you have the Jacobean. So, these input output velocity relations are linear and related through the Jacobean.

(Refer Slide Time: 12:11)

Diagram illustrating the velocity relations for a mechanism using instantaneous centers (IC) and the Jacobian method.

The diagram shows a mechanism with links 1, 2, 3, and 4. Link 1 is the ground, link 2 is a rotating link with length l_2 and angle θ_2 , link 3 is a slider on link 4 with length l_1 , and link 4 is a fixed link. Instantaneous centers I_{12} , I_{13} , and I_{24} are shown. Distances DB and DA are marked. The angle $\phi = \theta_2 - \theta_4$ is indicated.

Velocity relations are derived using the Jacobian method:

$$\dot{s} = \left[\left(\frac{DB - e}{DA} \right) l_2 \right] \dot{\theta}_2$$

$$\dot{s} = \left[\left(\frac{s \cos \phi - e \sin \phi}{s} \right) l_2 \right] \dot{\theta}_2 \Rightarrow \dot{s} = \underline{J} \dot{\theta}_2$$

$$\dot{\theta}_2 = \left[\left(\frac{s}{s \cos \phi - e \sin \phi} \right) l_2 \right] \dot{s} \Rightarrow \dot{\theta}_2 = \underline{J}^{-1} \dot{s}$$

Previously, we had also discussed the input output velocity relations using the method of IC which we just reiterate here we had used these 2 instantaneous centers of rotation.

So, this point d was I13. So, this is one this is 2 this is link 3 and this is link 4. So, this is I13 and this is I24 indicated by point c. And using these instantaneous centers, we had determined the input output velocity relations are the velocities velocity relations between a the expansion of the actuator, the expansion rate of the actuator and the angular rate of link 2.

So, I have written that out here DB and DA are these distances which you can show we can you can see on the figure. And using this angle ϕ where ϕ is nothing, but θ_2 minus θ_4 . Using this angle, we had expressed these velocity relations as I have shown here. So, these expressions of the Jacobean as defined from as defined in this slide. Looks very different or more complicated, so to say in when you compare it with that obtained from the analytical method. So, let us compare them.

(Refer Slide Time: 14:34)

Analytical method

$$\dot{\theta}_2 = \left[\frac{s}{l_1 l_2 \sin \theta_2} \right] \dot{s}$$

$$\dot{s} = \left[\frac{l_1 l_2 \sin \theta_2}{s} \right] \dot{\theta}_2$$

$J = 0$ when $s = 0$
 $\dot{\theta}_2 = 0$

• Vanishing of Jacobian: singularity
 • Dead-center/singular configurations

Method of IC

$$\dot{s} = \left[\left(\frac{s \cos \phi - e \sin \phi}{s} \right) l_2 \right] \dot{\theta}_2$$

$$\dot{\theta}_2 = \left[\left(\frac{s}{s \cos \phi - e \sin \phi} \right) l_2 \right] \dot{s}$$

$J^{-1} = 0$ when $\theta_2 = 0, \pi$
 $\dot{s} = 0$

So, these are the expressions of the velocity relations obtained from the analytical method and on the right, I have written out the velocity relations obtained from the method of ICs.

So, definitely these expressions on the left are more simple because here you have to determine phi. Now, vanishing of this Jacobian gives us the singularities of the kinematic chain and these singularities are nothing, but the dead center configurations of the chain. Now, specifying these or determining these dead center configurations was easier when we looked at the expressions obtained from the method of ICs, but these are also now quite easy if you look at the expressions obtained from the analytical method. So, let us look at the configurations where the Jacobian or its inverse vanishes which means they become singular or non-invertible. So, if I look at the Jacobian so, this is the Jacobian this is the Jacobian inverse.

So, when will the Jacobian vanish? The Jacobian will vanish when s equal to 0. So, j equal to 0 when S equal to 0. So, this was the configuration like this so, our chain so, from here if I start moving of course, the link lengths look a little different. So, when I start rotating the link 2 in the clockwise direction, there will come a situation where this revolute pair will start going into the prismatic pair. So, forgetting about the physical problems or the constructional problems, we can say that when this revolute pair gets into the prismatic pair if it can. Then S equal to 0 in that case that is a singular

configuration of the mechanism. So, in this singular configuration irrespective of the value of \dot{s} goes to 0.

So, at this configuration, $\dot{\theta}_2$ must be 0 you cannot move the link to, you cannot rotate it further, it must only move it can only reverse direction; that means, it can go only in the counterclockwise direction it cannot go any further in the clockwise direction. Whatever be the value of s , or \dot{s} ? It has to reverse direction the other singular configuration is for the Jacobean is when. So, here I have the Jacobean inverse. So, So, this s equal to 0 is the singularity of the Jacobean. When you look at Jacobean inverse, Jacobean inverse is equal to 0. When θ_2 is equal to 0 or π radian. You can very easily see because the numerator of Jacobean inverse has this $\sin \theta_2$.

So, that will vanish whenever θ_2 is 0 or π . And what are the configurations at which this will happen? So, when θ_2 equal to 0 so, this is one configuration. Here θ_2 equal to 0 and θ_2 is equal to π gives us this configuration. So, θ_2 equal to π radian gives us this configuration. So, what happens here? Irrespective of the value of $\dot{\theta}_2$ \dot{s} is 0. So, which means this actuator now cannot expand any further, it must reverse. So, it reaches a 0 velocity and it must now reverse back. So, in other words, here this while this link and rotate the this distance the distance s the rate of change of distance s is 0.

For example, if I move the link 2 in the clockwise direction, then s at this configuration, \dot{s} is 0. But, as you keep moving as the link to comes to such a position. So, s will contract. So, \dot{s} will be negative if you move in the other direction there also \dot{s} must contract. So, exactly at this configuration \dot{s} is 0. So, it has to reverse direction s has to reverse it is direction.

(Refer Slide Time: 23:13)

Key points

- Analytical input-output velocity relations
- Input-output velocity relations are linear
- Concept of **Jacobian**
- Singularity of Jacobian: **dead-center configurations**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, we have looked at the input output velocity relations for the chain of type 2. And obtained these linear velocity relations between the angular rate and the rate of expansion of the prismatic actuator. We have introduced or looked at this concept of Jacobean we found the expression of Jacobean following the analytical approach. And we have compared it with Jacobean obtained from the method of ICs or instantaneous center of rotation. And we have also discussed about the singularity of the Jacobean and the corresponding dead center configurations.

(Refer Slide Time: 24:03)

Displacement analysis: combination

INPUT

Input s, \dot{s}

Output $\theta, \dot{\theta}$

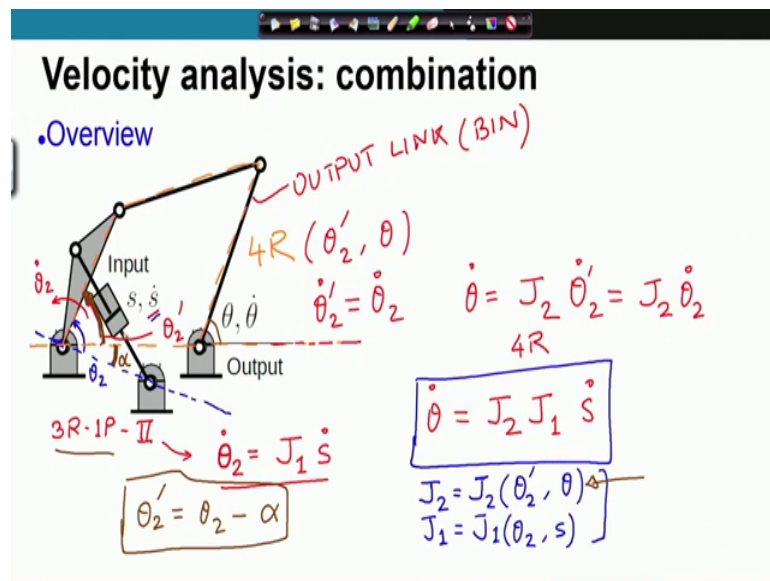

$4R_2$

$3R-1P-II$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, this approaches that we have been discussing. Now, can be combined to find out the velocity relations for more complicated chains. So, here I have this example of an excavator you can see, here that this if you focus on this part of the mechanism, it is akin to this kinematic chain. Where, the input is the prismatic actuator and output is the angular motion of the bin. So, you we have here you have here, this chain of type 2 and if you look at this mechanism this is a 4 R chain. So, a chain type 2 is driving a 4 R chain.

(Refer Slide Time: 25:51)

So, I will just briefly give you the idea of how we can analyze such mechanisms. Here, the ground hinge of the chain is this the ground link.

So, this is the line of frame, this was our theta 2 for the chain. Now, given the input in terms of S dot I can find out theta 2 dot. That we have seen I can relate S dot with theta 2 dot. For this chain of type 2 so, this we have derived. So, I have this relation theta 2 dot is equal to let me call it J1S dot. This we have derived this is for the chain now, this same theta 2 also acts as the input for the 4 R chain. The same theta 2 dot is the input to the 4 R chain. The only difference is the line of frame of this 4R chain is different. So, for the 4 R chain the line of frame is different, but theta 2 dot remains the same and the definition of theta 2 for the 4 R chain is also somewhat different.

let me show you so, this this is the angle theta 2 let me call it theta 2 prime. Let me call it theta 2 prime this theta 2 prime is the angle input angle for the 4 R chain. So, the input

is θ_2' and the output is θ_2 and of course, $\dot{\theta}_2$. Now $\dot{\theta}_2'$ is nothing, but $\dot{\theta}_2$ as you can see $\dot{\theta}_2'$ because the line of frame of the 4R chain is a fixed line is a fixed reference line. So, therefore, $\dot{\theta}_2'$ is also equal to $\dot{\theta}_2$.

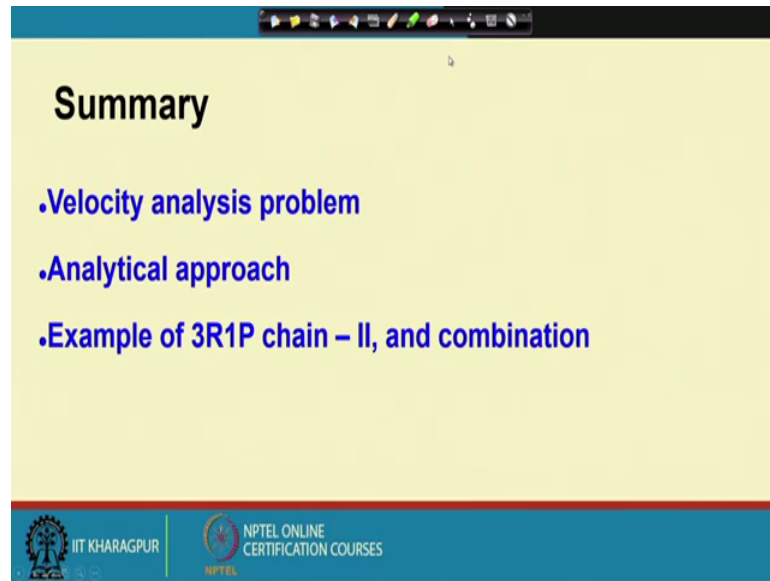

Now, given $\dot{\theta}_2'$ finding out $\dot{\theta}_2$ is the velocity relation for the 4R chain. So, that we already know. So, $\dot{\theta}_2$ is equal to J_2 which is for the 4R chain times $\dot{\theta}_2'$. So, this is for the 4R chain and that is also therefore, equal to $J_2 \dot{\theta}_2'$ and $\dot{\theta}_2$ we have already found in terms of \dot{S} therefore, $\dot{\theta}_2$ which is the velocity of the output link. So, this is our output which is the bin actually of the excavator.

So, $\dot{\theta}_2$ therefore, becomes $J_2 J_1 \dot{S}$. So, we have related the angular speed of the bin with the expansion rate of the prismatic actuator. Only thing to remember here, is that this J_2 is a function of θ_2 and θ_2' . So, J_2 will be a function of θ_2' and θ_2 and J_1 will be a function of θ_2 and S . So, this is the additional thing that has to be remembered you have to derive this which we have derived.

Now, the relation between θ_2 and θ_2' is also very simple. If you look here let us call this angle as α then, you can very easily see that θ_2' is equal to $\theta_2 - \alpha$. θ_2' which is this angle and θ_2 which is this blue angle they are related as θ_2' is equal to $\theta_2 - \alpha$, α is a fixed angle this is the angle between the lines of frame of the and 4R chains.

So, therefore, we have relation between θ_2' and θ_2 , which we can use in this expression and get everything in terms of θ_2 and S and θ_2 and s . Now, since this is a constraint mechanism given anyone let us say given S . I should be able to find out everything or given θ_2 which is the output angle I should be able to find out all the other angles and the value of S , which is the throw of the prismatic actuator. So, therefore, the analysis though a little extended now, is otherwise straightforward. It will involve lot of algebra, but otherwise the ideas are absolutely clear. So, just an extension of the analysis of these individual kinematic chains which we will we have used to analyze more complicated kinematic chain.

(Refer Slide Time: 34:01)

Summary

- Velocity analysis problem
- Analytical approach
- Example of 3R1P chain – II, and combination

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, let me summarize this lecture, we have considered the velocity analysis problem, we have taken the analytical approach to find out the input output velocity relations. We have analyzed the chain of type 2 and finally, I have shown you how the analysis of these fundamental chains, the basic chains can help you in the analysis of more complicated chains which can be broken down into these fundamental chains. So, we have followed the analytical velocity analysis approach.

Of course, for the combination you can also use the geometric approach, the final results will remain the same. So, I have shown you how to combine these various chains to have or get the velocity relations input output velocity relations for more complicated chains. So, with that I will conclude this lecture.
