Lecture – 38
Coordinate Transformation– I

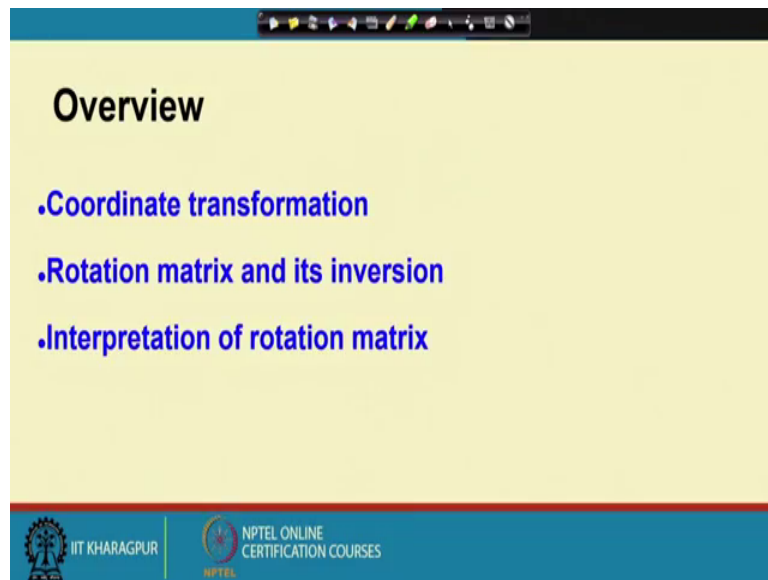

When we analyze multi degree of freedom systems like robots, we need to deal with multi input and multi output systems. Now, in a robot manipulator, as opposed to in a mechanism, in the constraint mechanism, we have various links moving in space or in a plane on manipulator various links moving in 1 plane. And they can change their position and orientation as they move.

Now, it is a very important thing in mechanics in general and kinematics, in particular to be able to track a point in a moving frame. So, for example, we always talk of this problem, that, suppose, there is a satellite or an aircraft which is in space which is flying and there is certain point which is moving with respect to the aircraft or with respect to the satellite, then the representation of motion of that point or particle is very easy in the aircraft frame or the satellite frame.

But, suppose, I want to represent this same motion in the earth fixed frame, then it becomes a little complicated. Now, for this, we use frame transformations, that simplifies the way we can relate these 2-this representation of vectors in a frame that might be moving in certain body which might be moving. So, we need to understand coordinates coordinate transformations in order to be able to represent a point or a particle or maybe another link, which is mounted on a moving link.

So, in this lecture, we are going to start discussions on coordinate transformation and we will see how this comes these concepts are used in very easily analyzing robot manipulators. In this in these lectures, we are going to restrict ourselves to the planar case. Once the planar case becomes clear, then going over to the special case of the 3-dimensional case becomes very simple. It is just a one step ahead.

(Refer Slide Time: 02:45)

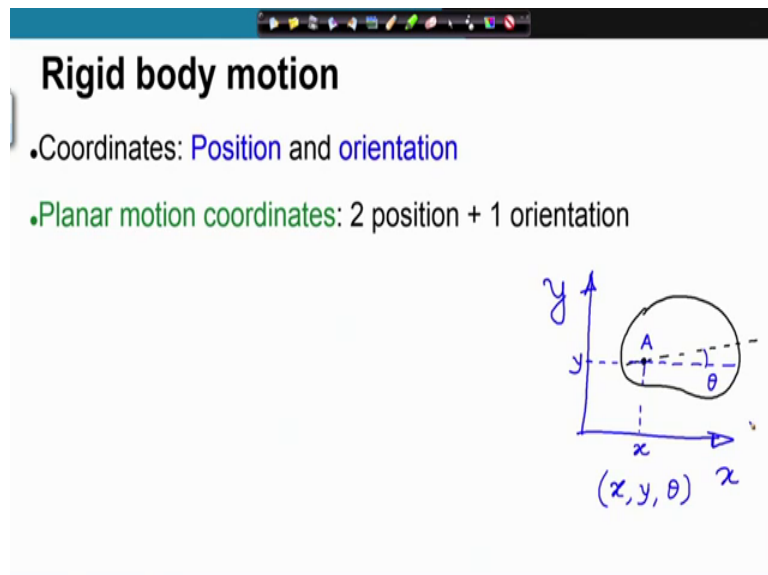

Overview

- Coordinate transformation
- Rotation matrix and its inversion
- Interpretation of rotation matrix

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

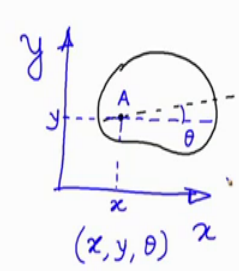

So, the overview of this lecture is that, we are going to first start with the coordinate transformation, we are going to look at rotation matrix and its inversion and we are going to interpret the rotation matrix, so that, we are able to understand the elements that construct the rotation matrix.

(Refer Slide Time: 03:05)

Rigid body motion

- Coordinates: Position and orientation
- Planar motion coordinates: 2 position + 1 orientation

(x, y, θ)

Now, rigid body motion is tracked by certain coordinates. So, how do you track a body moving in space a rigid body moving in space; or on the on the plane?

So, we have coordinates which are the position and orientation coordinates of the body. So, the position coordinates can be xyz and the orientation coordinates can be rotations about the 3 axis. There are various ways of representing orientation. Here, we are going to only restrict ourselves to planar orientation. So, the in planar motion coordinates, we have 2 positions and 1 orientation.

So, let me show you what I mean. So, in the plane, let us say, the xy plane, if I have a body, so, this dashed line is fixed to the body. Then, by tracking the xy of this point, let us say A on the body and the orientation through this angle let us say θ . So, this angle θ is the angle measured between the body fixed line and the x axis. So, we have these 3 coordinates $x y \theta$. So, by keeping track of $x y$ and θ , I can uniquely locate the body in a plane. So, we have 2 positions and 1 orientation coordinate for planar motion.

(Refer Slide Time: 05:19)

Rigid body motion

- Coordinates: Position and orientation
- Planar motion coordinates: 2 position + 1 orientation
- Spatial motion coordinates: 3 position + 3 orientation

The diagram shows a 3D Cartesian coordinate system with axes labeled x , y , and z . A blue line is drawn in the xy plane, representing a body's orientation. A point on this line is labeled (x, y, z) . Another point is labeled $(\gamma_x, \gamma_y, \gamma_z)$, representing direction cosines. The z axis is also labeled with a z .

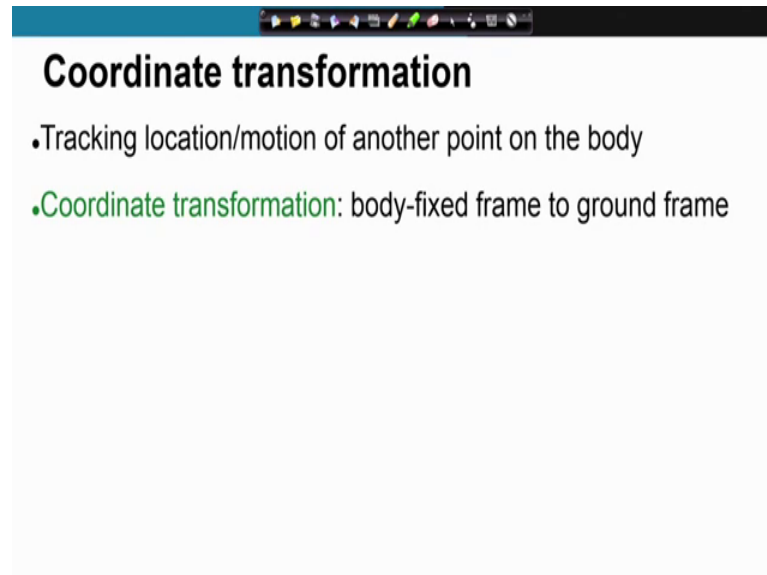

For spatial motions, we require 3 position coordinates and 3 orientations coordinates.

Suppose, I have a body in which a line is fixed, then I can locate coordinates of a certain point on the body and the orientation by looking at possibly the direction cosines, these angles, that the line makes with the local xyz coordinate system, which is parallel to the blue coordinate system.

So, by having this these angles, let us say, γ_x , γ_y , γ_z , I can fix the position of the body. So, x, y, z and $\gamma_x, \gamma_y, \gamma_z$, these will fix the

position and orientation of the body in space. So, I and acquire 6 coordinates for a body in space.

(Refer Slide Time: 07:07)

The image shows a presentation slide with a blue header bar and a black toolbar. The slide content is as follows:

Coordinate transformation

- Tracking location/motion of another point on the body
- **Coordinate transformation:** body-fixed frame to ground frame

Now, in order to track the location or motion of a point on a body which is in motion may be in play on the plane or in space. So, if I have a body which is moving in space, let us say, and there is something else which is also moving with respect to that body. I would like to find out the coordinates of that point in my earth fixed frame. So, this is what I want to find out. So, I want to track the location on motion of another point on the body. So, for that I require coordinate transformation. So, this coordinate transformation, we will take the coordinates of the point in the body fixed frame to the ground frame. So, that is the purpose of the coordinate transformation.

(Refer Slide Time: 08:03)

Coordinate transformation: plan

- Rotational transformation: planar case
- Homogeneous coordinate transformation: planar case
- Application to open-chain robot kinematics

Now, our plan for coordinate transformation I have listed out here. So, we will begin by looking at the rotational transformation; the planar case, then we will look at the homogenous coordinate transformation in the in the plane and we will finally, we will look at applications of the concept of coordinate transformation for analysis of robot open loop open chain robots.

(Refer Slide Time: 08:40)

Rotational transformation

- Vector in a plane: representation and projection

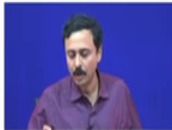

$\vec{p} = p_x \hat{i} + p_y \hat{j}$

Projection of \vec{p} along \hat{a}

$\hat{a} = c\theta \hat{i} + s\theta \hat{j}$

$\vec{p} \cdot \hat{a} = (p_x \hat{i} + p_y \hat{j}) \cdot (c\theta \hat{i} + s\theta \hat{j})$
 $= p_x c\theta + p_y s\theta$

$\vec{p} \cdot \hat{i} = p_x$

So, we will start with discussing the rotational transformation. Let us consider a vector in the plane. As I have shown you here, so this p_x is a vector. So, a P is a vector in the plane

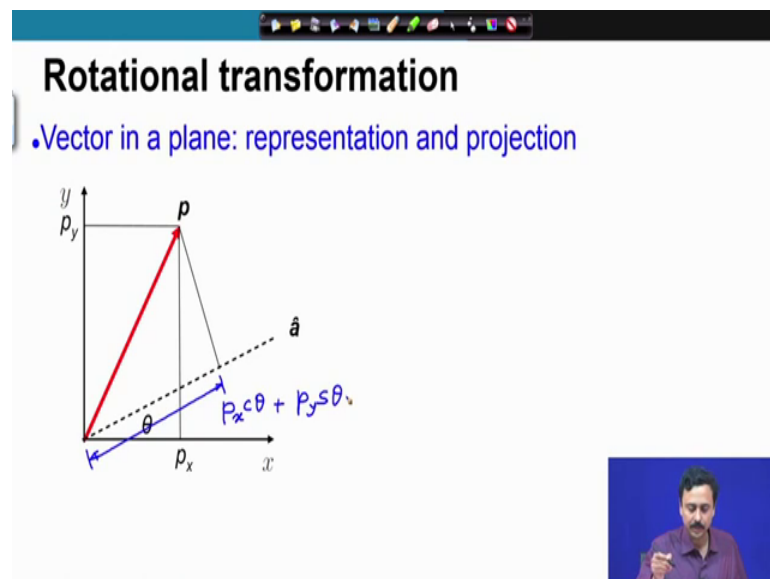

with coordinates p_x and p_y . So, normally, we tend to represent this vector p as $p_x \hat{i}$ plus $p_y \hat{j}$. Now, this P is a position vector suppose and suppose, it is a position vector of a point P . So, the vector p is a position vector of a point P .

Let us consider a direction. Here, I have represented as a cap which is at an angle θ . I would like to find the projection of the vector p along a cap. So, I want to find out the projection of the vector p along the unit vector \hat{a} . Now, you already know and we have also discussed the concept of projection. For example, if I want to project the vector p along x axis then, so if I want to project vector p along x axis, then I take a dot product with \hat{i} and that gives me p_x .

Now, our problem is little more general. We have a unit vector \hat{a} , which is the direction at an angle θ with respect to the x axis. Therefore, I can very easily represent the unit vector \hat{a} . So, cosine θ , I am writing $c \theta$ for cosine θ \hat{i} plus $\sin \theta$ I will write $s \theta$ for sin θ times \hat{j} . So, that is the unit vector \hat{a} .

So, therefore, projection of p along \hat{a} , is nothing but the dot product of p vector with \hat{a} . So, this is the p vector and \hat{a} vector is and that gives us $p_x \cos \theta$ plus $p_y \sin \theta$. So, that is the dot product of p with \hat{a} . And this is this concept is what we are going to use for constructing the rotational transformation. So, let us see, how we do that.

(Refer Slide Time: 12:27)

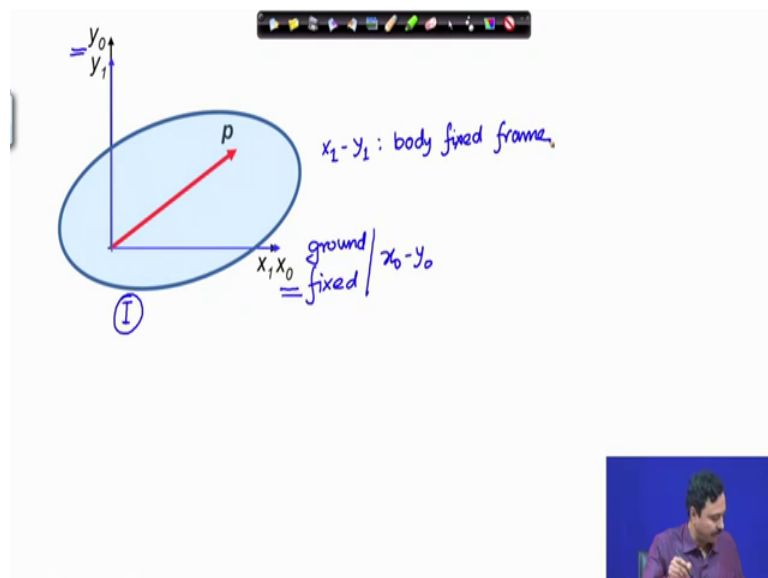

So, this projection, so this distance, is nothing but what I just now wrote out $p \times \cos \theta$ plus $p_y \sin \theta$. So, that is the projection and this is what we are going to use.

(Refer Slide Time: 12:48)

So now, we are going to directly go into the problem of tracking a point on a rotating body.

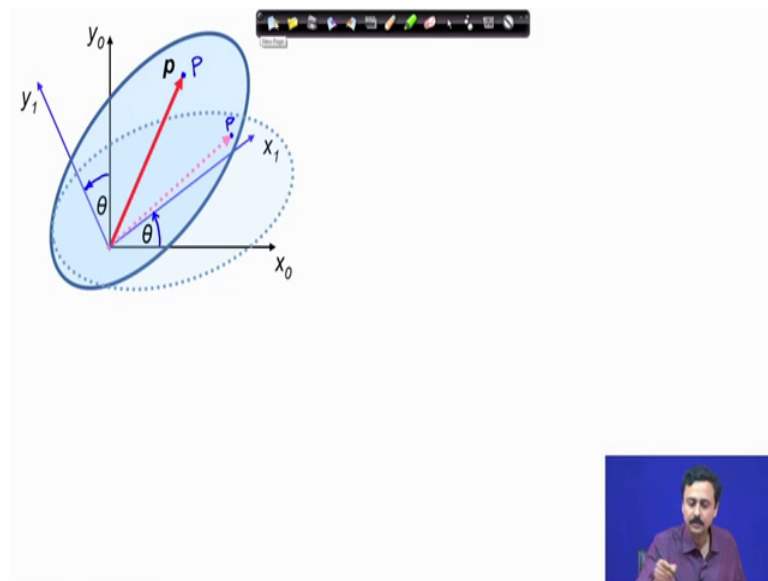

(Refer Slide Time: 13:57)

So, here, I have shown you a body in position 1 which rotates and goes over to position 2. There is a point P on the body, whose position vector is this vector p .

So, this point p goes over here, upon rotation. And the new vector is again represented here as p . So, p vector represents the position of the point P . Here, I have shown you the body in configuration 1. So, this is configuration 1 and I have also shown 2 frames. Here is 1 frame $x_0 y_0$ which we will fix this is ground fixed. So, $x_0 y_0$ is ground fixed. The $x_0 y_0$ frame is ground fixed, whereas, the frame $x_1 y_1$ is body fixed. So, the frame $x_1 y_1$ is body fixed and $x_0 y_0$ is ground fixed. What happens when we rotate the body ?

(Refer Slide Time: 15:12)

$x_1 y_1$ has rotated by this angle θ as you can see. This was the initial position of point P . And now, the new position of point P is here. Our objective is to locate the new point P in $x_0 y_0$. Here, I have removed the original position of the body in configuration 1. So, we can only see the body in configuration 2. The body fixes frame $x_1 y_1$ and the ground fixed frame $x_0 y_0$. We can also see the new location of point P .

(Refer Slide Time: 16:22)

$$p = p_x^0 \hat{i}_0 + p_y^0 \hat{j}_0 \leftarrow$$

$$p = p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1 \leftarrow$$

$$p_x^0 = \vec{p} \cdot \hat{i}_0$$

$$= (p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1) \cdot \hat{i}_0$$

$$= p_x^1 (\hat{i}_1 \cdot \hat{i}_0) + p_y^1 (\hat{j}_1 \cdot \hat{i}_0)$$

$$= p_x^1 \cos \theta + p_y^1 \cos(90^\circ + \theta)$$

$$= p_x^1 \cos \theta + p_y^1 (-\sin \theta)$$

$$p_x^0 = p_x^1 \cos \theta - p_y^1 \sin \theta$$

$$p_y^0 = \vec{p} \cdot \hat{j}_0$$

$$= (p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1) \cdot \hat{j}_0$$

$$p_y^0 = p_x^1 \sin \theta + p_y^1 \cos \theta$$

So, this is the new location of point P. What I want to determine is, this p x represented in frame 0 and p y represented in frame 0. In terms of p x represented in frame 1 and p y represented in frame 1.

Therefore, I have these 2 representations of the vector p. Remember that, it is the same vector p, which is the position vector of point P; P. In the ground fixed frame, the representation of the vector p is $p_x^0 \hat{i}_0 + p_y^0 \hat{j}_0$, where \hat{i}_0 and \hat{j}_0 are unit vectors along x_0 and y_0 . And similarly, in frame one the representation of the same vector p is $p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1$.

Remember, this is the same vector p being represented in 2 different frames. Nothing else. And we would like to find out the relation between this p_x^0, p_y^0 and p_x^1, p_y^1 . This is what our objective is. Now, how do we go about doing this? I want to find out p_x^0 . So, how do I find out p_x^0 ? Is nothing but the vector p dot \hat{i}_0 ; that is, p_x^0 . Now, p has this representation in the new frame, like this and this dot \hat{i}_0 . So, this becomes $p_x^1 \hat{i}_1 \cdot \hat{i}_0 + p_y^1 \hat{j}_1 \cdot \hat{i}_0$. So, this becomes p_x^1 .

Now, what is $\hat{i}_1 \cdot \hat{i}_0$? $\hat{i}_1 \cdot \hat{i}_0$. Remember that \hat{i}_1 is \hat{i}_1 cap is along x_1 and \hat{i}_0 cap is along x_0 . So, what is the dot product of 2-unit vectors which has angle theta between them? Is nothing but the cosine of the angle between the 2 vectors? So, this must be cosine theta plus p_y^1 .

Now, $\hat{j}_1 \cdot \hat{i}_0$. So, \hat{j}_1 is nothing but a unit vector along y_1 now, this unit vector \hat{j}_1 I have drawn here dot \hat{i}_0 . So, it must be cosine of the angle between \hat{i}_0 and \hat{j}_1 . Now that angle is $90^\circ + \theta$ as you can see. You have 90° plus θ that is the angle between \hat{i}_0 and \hat{j}_1 . So, this becomes cosine of the angle between the 2 which is $90^\circ + \theta$. So, that becomes $p_x \cos(90^\circ + \theta) + p_y \sin(90^\circ + \theta)$.

Now, cosine of $90^\circ + \theta$ is nothing but minus of $\sin \theta$. So, therefore, this becomes $p_x \cos(90^\circ + \theta) = -p_x \sin \theta$. So, this is $p_x \sin \theta$ in terms of p_x and p_y . So, we have related p_x^0 in terms of p_x^1 and p_y^1 . So, we have one relation. Now, we obtained one relation between p_x^0 and p_x^1, p_y^1 in terms of the rotation of the frames θ .

Now, following this procedure, I can find out also p_y^0 . The procedure remains the same; which means, I must have p_y^0 as $\hat{p} \cdot \hat{j}_0$. And then, once again, I use the representation in frame 1 carry out the dot product write out the angles between the unit vectors and I will get a second relation. So, that will turn out to be I will have $\hat{i}_1 \cdot \hat{j}_0 = \sin \theta$ that is the angle. So, because both are unit vectors.

So, it is the cosine of the angle between \hat{i}_1 and \hat{j}_0 . So, that will be cosine of $90^\circ - \theta$, which means, this will be $\sin \theta$. And then I will have $p_y^1 \sin \theta + p_x^1 \cos \theta$. So, this will become cosine θ this you can easily check.

(Refer Slide Time: 24:26)

$$\vec{p} = p_x^0 \hat{i}_0 + p_y^0 \hat{j}_0$$

$$\vec{p} = p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1$$

$$\begin{Bmatrix} p_x^0 \\ p_y^0 \end{Bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{Bmatrix} p_x^1 \\ p_y^1 \end{Bmatrix}$$

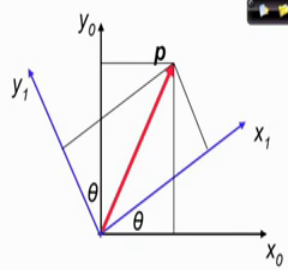

$$\vec{p}^0 = R_1 \vec{p}^1$$

Rotation matrix

So, I have finally, these relations. So, let me show these things formally. So, I have these relations. I have shown you how to obtain these relations. Now, I will assemble them p_x^0 p_y^0 I will write as a column vector is equal to some matrix times p_x^1 p_y^1 . Because I have these 2 relations, on the left we have p_x^0 p_y^0 and on the right, we have p_x^1 p_y^1 . So, I have written them as matrix times p_x^1 p_y^1 and if you fill in the elements of these of this matrix from the individual relations you will obtain this matrix.

Therefore, I will write this in a compact form as p vector represented in frame 0 as the rotation matrix which takes me from frame 1 to frame 0 times p represented in frame 1. So, this is how we are going to represent these vectors and show in which frame they are represented in. So, this p^1 is represented in frame 1 p^0 is represented in frame 0 and they are related through the rotation matrix R from 1 to 0. So, we will always say it goes from 1 to 0. So, on the right-hand side, I will x vector represented in 1 in frame 1 and on the left, I will get a vector represented in frame 0. So, this is the implication.

(Refer Slide Time: 26:49)

$$p = p_x^0 \hat{i}_0 + p_y^0 \hat{j}_0$$

$$p = p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1$$

$$p_x^0 = p \cdot \hat{i}_0 = p_x^1 \hat{i}_1 \cdot \hat{i}_0 + p_y^1 \hat{j}_1 \cdot \hat{i}_0$$

$$\Rightarrow p_x^0 = p_x^1 (\cos \theta) + p_y^1 (-\sin \theta)$$

$$p_y^0 = p \cdot \hat{j}_0 = p_x^1 \hat{i}_1 \cdot \hat{j}_0 + p_y^1 \hat{j}_1 \cdot \hat{j}_0$$

$$\Rightarrow p_y^0 = p_x^1 (\sin \theta) + p_y^1 (\cos \theta)$$

$$\begin{Bmatrix} p_x^0 \\ p_y^0 \end{Bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{Bmatrix} p_x^1 \\ p_y^1 \end{Bmatrix}$$

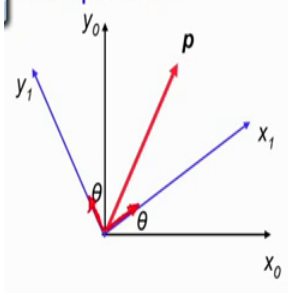

$$p^0 = {}^0R_1 p^1$$

So, just to show this thing formally.

(Refer Slide Time: 26:54)

Rotation matrix

• Interpretation

$$p^0 = R_1 p^1$$
$$\begin{Bmatrix} p_x^0 \\ p_y^0 \end{Bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{Bmatrix} p_x^1 \\ p_y^1 \end{Bmatrix}$$

Representation of y_1 in x_0-y_0

Representation of x_1 in x_0-y_0

Now, we interpret this rotation matrix. If you look at column 1 of the rotation matrix, the column 1 you can very easily see is the representation of the vector x_1 or the axis x_1 in $x_0 y_0$.

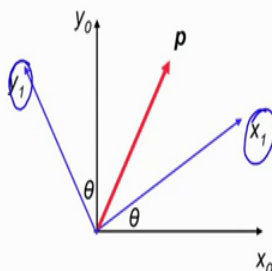

The column 1 is the unit vector along x_1 being represented in $x_0 y_0$. So, this unit vector being represented in $x_0 y_0$ is nothing but that first column of the rotation matrix. The second column is the representation of the unit vector along y_1 in $x_0 y_0$. So, I will write this is the representation of y_1 in $x_0 y_0$ frames.

Now, if I interpret that this way, then it is very easy to construct the rotation matrix. I need not go through the steps that I have just now shown you. I can directly construct the rotation matrix. So, remember that, the 1st column of the rotation matrix that takes me from 1 to 0 is nothing but the representation of the frames $x_1 y_1$ in $x_0 y_0$. So, the first column is representation of x_1 in $x_0 y_0$. The 2nd column is the representation of y_1 in $x_0 y_0$. So, that will construct the rotation matrix 1 to 0.

(Refer Slide Time: 29:16)

Rotation matrix

- Direct construction
- Column 1: representation of x_1 in x_0 - y_0 frame
- Column 2: representation of y_1 in x_0 - y_0 frame

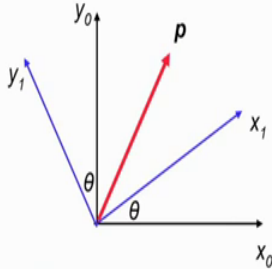

$${}^0R_1 = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}$$

So, we can directly construct the rotation matrix. Let me do that. So, I say, that I want to construct this rotation matrix from 1 to 0 that will take me from frame 1 to frame 0, then I must represent the individual axis of the frame 1 in frame 0. So, frame 1 the first axis is x_1 . So, let me represent x_1 in x_0 y_0 .

So, this will be cosine theta sin theta and then, the 2nd column is the representation of y_1 in x_0 y_0 . So, that is minus sin theta cosine theta.

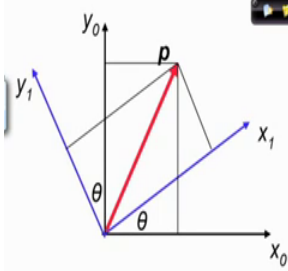

(Refer Slide Time: 30:07)

Inversion of rotation matrix

Now, when we invert the rotation matrix, is just the opposite thing that you do, you start with the vector representation in the 2 frames.

(Refer Slide Time: 30:13)

$$p = p_x^0 \hat{i}_0 + p_y^0 \hat{j}_0$$

$$p = p_x^1 \hat{i}_1 + p_y^1 \hat{j}_1$$

$${}^1R_0 = ({}^0R_1)^T$$

$$\vec{p}^1 = {}^1R_0 \vec{p}^0$$

$$\begin{Bmatrix} p_x^1 \\ p_y^1 \end{Bmatrix} = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix} \begin{Bmatrix} p_x^0 \\ p_y^0 \end{Bmatrix}$$

$$p^1 = ({}^0R_1)^{-1} p^0 = ({}^0R_1)^T p^0$$

$$p_x^1 = p \cdot \hat{i}_1 = p_x^0 \hat{i}_0 \cdot \hat{i}_1 + p_y^0 \hat{j}_0 \cdot \hat{i}_1$$

$$\Rightarrow p_x^1 = p_x^0 (\cos \theta) + p_y^0 (\sin \theta)$$

$$p_y^1 = p \cdot \hat{j}_1 = p_x^0 \hat{i}_0 \cdot \hat{j}_1 + p_y^0 \hat{j}_0 \cdot \hat{j}_1$$

$$\Rightarrow p_y^1 = p_x^0 (-\sin \theta) + p_y^0 (\cos \theta)$$

now you do a dot product with \hat{i}_1 to get p_x in frame 1. So, that is the only difference.

Now, if you proceed this way, similarly, we will get p_y in frame 1 and therefore, finally, you can represent this vector p in frame 1. So, therefore, this must be the rotation matrix that takes me from frame 0 to frame 1 and p that must be multiplied by the vector p in frame 0 and that is being represented here. You can very easily check that R from 0 to 1 is the transpose of R from 1 to 0. R from 0 to 1 is nothing but R from 1 to 0 transpose and that expression you have here.

(Refer Slide Time: 31:36)

Inversion of rotation matrix

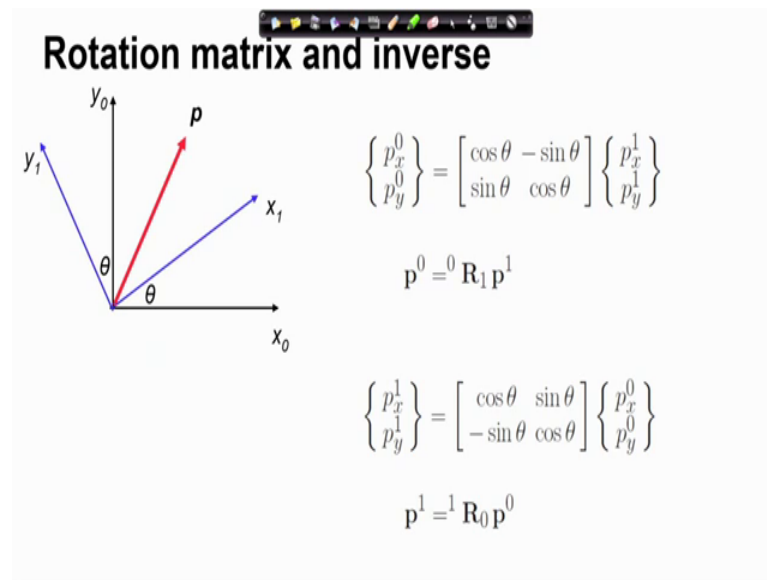

- Direct construction
- Column 1: representation of x_0 in x_1 - y_1 frame
- Column 2: representation of y_0 in x_1 - y_1 frame

$${}^1R_0 = \begin{bmatrix} \underbrace{c\theta}_{x_0 \text{ in } x_1-y_1} & \underbrace{s\theta}_{y_0 \text{ in } x_1-y_1} \\ -s\theta & c\theta \end{bmatrix} = ({}^0R_1)^T$$

So, therefore, once again a direct construction let us look at it in direct construction of R from 0 to 1. So, what do I now have to do? I have to represent the frame $x_0 y_0$ in $x_1 y_1$. So, frame the axis x_0 the first column will be axis x_0 in $x_1 y_1$. So that, you can easily check is cosine theta this angle being theta. So, cosine theta and minus sin theta that represents x_0 in $x_1 y_1$.

The second column is representation of y_0 in $x_1 y_1$. So, the second column is representation of y_0 in $x_1 y_1$. So, y_0 in $x_1 y_1$, now this being theta, so, I must have sin theta and cosine theta this is y_0 in $x_1 y_1$. So, that constructs the rotation matrix R from 0 to 1 and that you can check is the transpose of the matrix R from 1 to 0.

(Refer Slide Time: 33:09)

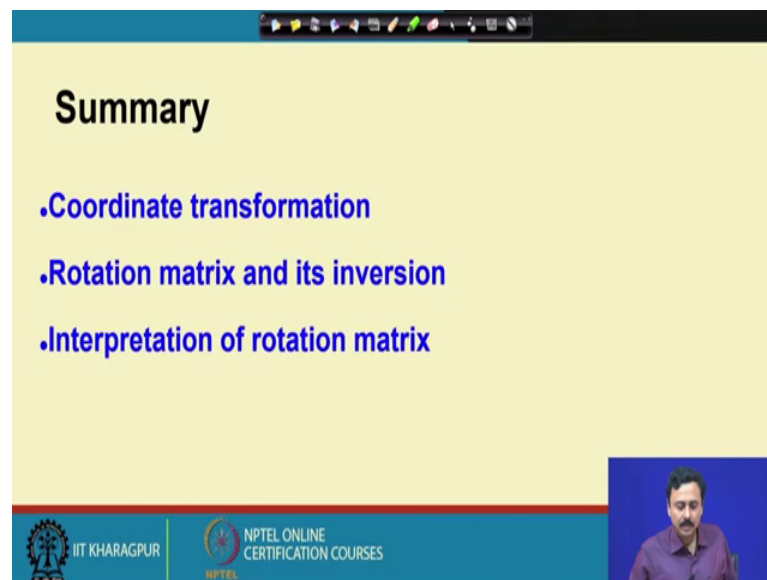

Rotation matrix and inverse

$$\begin{Bmatrix} p_x^0 \\ p_y^0 \end{Bmatrix} = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \begin{Bmatrix} p_x^1 \\ p_y^1 \end{Bmatrix}$$
$$\mathbf{p}^0 = {}^0R_1 \mathbf{p}^1$$
$$\begin{Bmatrix} p_x^1 \\ p_y^1 \end{Bmatrix} = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix} \begin{Bmatrix} p_x^0 \\ p_y^0 \end{Bmatrix}$$
$$\mathbf{p}^1 = {}^1R_0 \mathbf{p}^0$$

So, therefore, here I have written out the direct and the inverse rotation matrices from frame 0 to 1 and 1 to 0.

(Refer Slide Time: 33:26)

Summary

- Coordinate transformation
- Rotation matrix and its inversion
- Interpretation of rotation matrix

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, let me summarize what we have discussed in this lecture. We have looked at coordinate transformations, we have looked at the basis of coordinate transformation and why we need it. I have constructed I have shown you how to construct the rotation matrix and I have also given you the interpretation of the rotation matrix. And this interpretation helps us to directly write the rotation matrix by looking at the coordinate

frame orientations. And we are going to use this rotation matrix in our subsequent discussions. I will close this lecture at this point.
