Lecture – 32
Acceleration Analysis – I

In this lecture we are going to start our discussions on Acceleration Analysis. Till now we have looked at motion of mechanisms and robots from displacement and velocity perspectives. In this lecture we are going to start our discussion on Acceleration analysis.

(Refer Slide Time: 00:43)

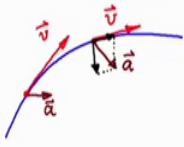

Now, to give you an overview of what we are going to discuss in this lecture will look at the acceleration analysis problem and formulate the analytical approach and will study this through examples of 4R chain and the 3R1P chain of the of type 1.

(Refer Slide Time: 01:09)

Acceleration analysis

- Mechanism transforms actuator motion input(s) to motion of output link
- Motion: characterized by displacement, velocity and acceleration
- Requires completion of displacement and velocity analysis
- Acceleration analysis is non-intuitive!

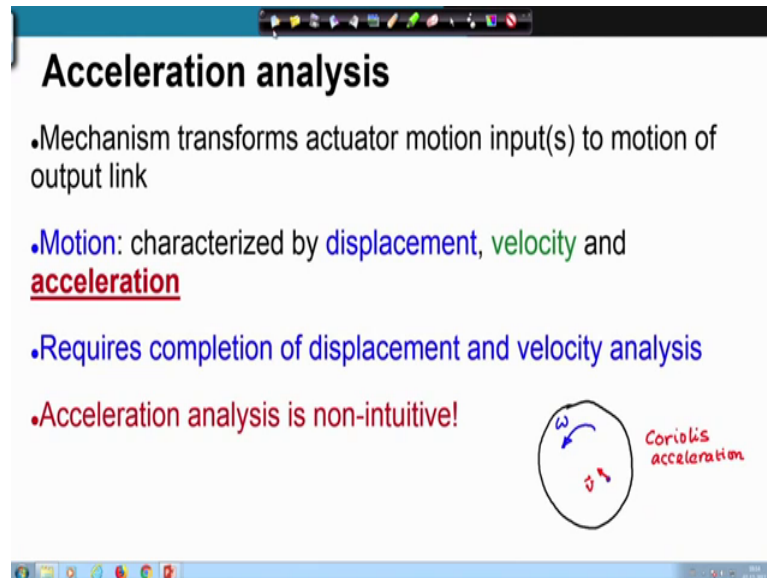

Now, as you know that a mechanism transforms actuator motion which are the inputs to motion of the output link. Now motion is characterized by displacement, velocity and acceleration. So, we have discussed displacement, we have discussed velocity, so these 2 characterize motion. The next characterization comes from acceleration. So, in acceleration we assume that the displacement and velocity analysis has been completed.

So, before we embark upon acceleration analysis we require displacement and velocity analysis to be completed. Now acceleration analysis is non intuitive what do I mean by that? So, if you consider a point moving on a certain trajectory then you know that the velocity of this point at any point on the trajectory is tangential to the trajectory, but there is no such restrictions on acceleration and that makes it non intuitive.

So, what I mean by this let us consider a trajectory on which particle is moving. So, at any point the velocity is definitely restricted along the tangent to the trajectory at that point, so at any point the velocity vector must be tangent to the path at that point. But when you look at acceleration, acceleration can have an arbitrary direction. So, acceleration on a path can have an arbitrary direction but velocity must always be tangent to the path. Now this makes acceleration non intuitive. As you know that this can have 2 components, this acceleration can have a component along the path and perpendicular to the path. The tangential acceleration results in increase of the speed, whereas this perpendicular component is because of the path curvature. There is another

possibility which occurs in rotating frames or in bodies which are rotating let us say you have a disc on which you have a particle.

(Refer Slide Time: 04:55)

Acceleration analysis

- Mechanism transforms actuator motion input(s) to motion of output link
- Motion: characterized by displacement, velocity and acceleration
- Requires completion of displacement and velocity analysis
- Acceleration analysis is non-intuitive!

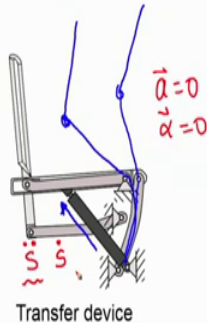

Coriolis acceleration

The disc is rotating at a constant speed ω in this plane let us say and this point has a velocity. Assume that this velocity is also constant, I mean with respect to the disc even then this point has acceleration as we know this point has acceleration which is known as the Coriolis acceleration because this point this particle has a velocity in a rotating frame. So, this is rotating disc is rotating and the particle is moving with a velocity with respect to the disc. Even though, ω is constant and v is constant this particle has acceleration, so this makes acceleration non intuitive.

(Refer Slide Time: 06:19)

Acceleration analysis: motivation

- Connection to **dynamics**
- Kinematic requirement on output motion

The diagram shows a mechanical linkage system labeled "Transfer device". It consists of a horizontal bar pivoted at its left end to a fixed base. A vertical link is attached to the right end of this bar. A second horizontal link is attached to the vertical link. A blue arrow indicates the input motion at the base of the first horizontal link. Handwritten red annotations include $\ddot{a} = 0$ and $\ddot{\alpha} = 0$ near the vertical link, and $\ddot{s} \sim \ddot{s}$ near the base of the first horizontal link.

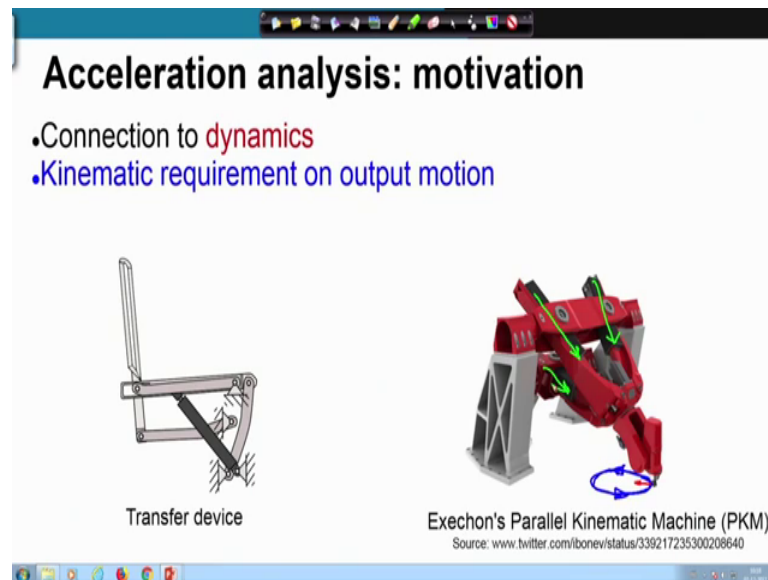

Transfer device

Now, why should we study acceleration analysis? First point definitely that comes to your mind is it is connected to dynamics we know Newton's second law it requires acceleration. It is a connection between acceleration and force. So, in order to relate to dynamic or go over to dynamics we need acceleration, acceleration of centre of mass of the links. But there is another reason why we must study acceleration we have to go to acceleration analysis, to understand this kinematic requirement on output motion of a mechanism or a robot now what do I mean by this?

Let us consider this transfer device as we have discussed when this actuator expands, this device is going to straighten out so this device is going to move. Now if I want that there should not be any acceleration at the output of certain point let us say or maybe angular acceleration is 0, in that case I must have restrictions on this expansion rate of this actuator. The restriction comes from the acceleration of the actuator acceleration of expansion of the actuator, so if I want acceleration at the output to be 0 there must be some definite acceleration at the input.

If I want some non-zero acceleration at the output then also I have to decide on the acceleration I have to know what should be the acceleration at the input, so that it produces for example a constant acceleration. So therefore, we need to understand the acceleration input output relation for this transfer device.

(Refer Slide Time: 09:01)

The same holds for this parallel kinematic machine, suppose I want to move the tool on a certain circular path, let us at a constant speed even though the tooltip is moving at a constant speed on a circular path it has acceleration the centripetal acceleration. So therefore, I must have certain acceleration at the actuator expansion as well.

(Refer Slide Time: 09:57)

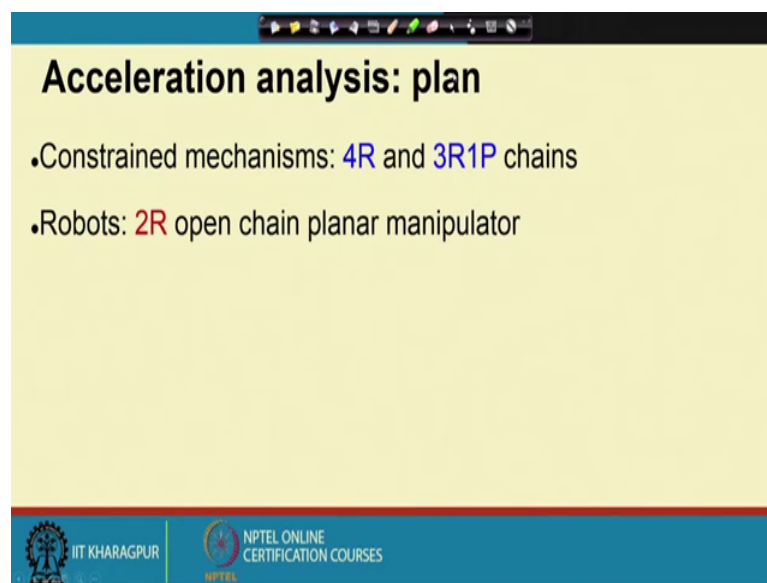

So, what we need is to understand the acceleration input output relation. So, the acceleration problem analysis problem is essentially relating the actuator acceleration with output link acceleration, so this is what the problem is about. So, what are they

given. We are given the analytical displacement and velocity relations and we have to find out the acceleration relation.

So, here let us say in this excavator we are given or we know already that we the displacement relations of the bend in terms of the actuator expansion we also know the velocity relations. So, if I want to produce the certain velocity at the output what should be the expansion rates at the actuators at these 2 actuators, so then we can embark upon the acceleration analysis.

Acceleration analysis: plan

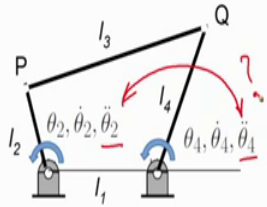

- Constrained mechanisms: 4R and 3R1P chains
- Robots: 2R open chain planar manipulator

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, our plan for acceleration analysis is given here will first discuss constraint mechanisms 4R and 3R1P chains after that we are going to move to 2R open chain planar manipulators.

(Refer Slide Time: 11:41)

Acceleration analysis: 4R chain

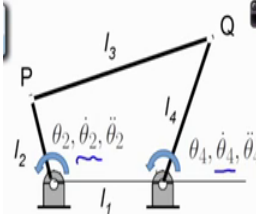

- Configuration (θ_2, θ_4) : displacement analysis ✓
- Velocity relation $(\dot{\theta}_2, \dot{\theta}_4)$: velocity analysis
- To determine expression relating $\ddot{\theta}_2$ and $\ddot{\theta}_4$?

So, here I have an image of this 4R chain. We already know the configuration. So, theta 2 and theta 4 are given and this relation is through the displacement analysis from the velocity analysis we know the relation between theta 2 dot and theta 4 dot. Then we have to find out the relation between theta 2 double dot and theta 4 double dot, so we have to relate these 2. So, this is our Acceleration analysis problem.

(Refer Slide Time: 12:37)

Analytical velocity relation

$$\dot{\theta}_4 = \left(\frac{l_2}{l_4} \right) \left[\frac{l_4 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_2}{l_2 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_4} \right] \dot{\theta}_2$$

$$\dot{\theta}_4 = J \dot{\theta}_2 \quad J(\theta_2, \theta_4)$$

Time differentiating both sides

$$\ddot{\theta}_4 = \dot{J} \dot{\theta}_2 + J \ddot{\theta}_2$$

$$J = J(\theta_2, \theta_4)$$

$$\dot{J} = \frac{\partial J}{\partial \theta_2} \dot{\theta}_2 + \frac{\partial J}{\partial \theta_4} \dot{\theta}_4 = \left[\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4} J \right] \dot{\theta}_2$$

So, let us start with the velocity relation. So, here I have written out for you the analytical velocity relation which we have already discussed. Now here I have an

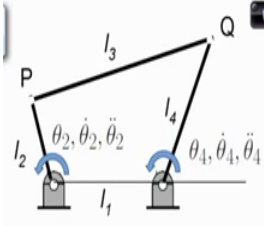

important point to mention we have done this velocity analysis by 2 approaches, we had first discussed about the method of ICs or Instantaneous Centre's of Rotation. So, using the concept of instantaneous centre of rotation we have related the velocity at the input with the velocity at the output, subsequently we discussed analytical velocity input output relations.

Now when we discuss this method of ICs remember that, that velocity analysis depended on the location of the insisting a centre of rotation. Now when we come to acceleration analysis it is the comparison of velocity of 2 infinitesimally separated configurations of the mechanism. Now when I move the mechanism from a certain configuration to another configuration you must remember that the IC has also shifted. So therefore, when I discuss acceleration analysis the method of ICs is more complicated because I must also take into account the variation of the IC itself the movement of the IC itself.

So therefore, this being complicated we will take recourse to the analytical velocity analysis and we will start from there for our acceleration analysis and that is what we are going to do here. So here, I have written out the analytical velocity relation that we have derived. So, I have the output velocity so this is the output θ_4 dot is the output and θ_2 dot is the input, so the input output velocity relations as you know is related through the Jacobean and the Jacobean is a scalar in this case. Now when you are differentiate both sides of this expression with respect to time you have this relation. Remember that the Jacobean is a function of θ_2 and θ_4 .

So therefore, when I time differentiate the input output velocity relation I also differentiate the Jacobean. So, Jacobean is a function of θ_2 and θ_4 . So, the rate of change of Jacobean I can write as $\frac{dJ}{dt} = \frac{\partial J}{\partial \theta_2} \dot{\theta}_2 + \frac{\partial J}{\partial \theta_4} \dot{\theta}_4$. So, using chain rule I have this expression of J dot. Now you will notice that $\dot{\theta}_4$; $\dot{\theta}_4$ is again J times $\dot{\theta}_2$. So therefore, this expression I can simplify and write by taking $\dot{\theta}_2$ out common. So, this is the expression of J dot $\frac{dJ}{dt}$ the time derivative of the Jacobean is therefore this expression. Now this I will substitute here and let us see what we have.

(Refer Slide Time: 17:35)

Anal velocity relation

$$\dot{\theta}_4 = \left(\frac{l_2}{l_4} \right) \left[\frac{l_4 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_2}{l_2 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_4} \right] \dot{\theta}_2$$

$$\dot{\theta}_4 = J \dot{\theta}_2$$

Time differentiating both sides

$$\ddot{\theta}_4 = J \ddot{\theta}_2 + f(\theta_2, \theta_4) \dot{\theta}_2^2$$

- Inhomogeneous
- Linear

$$J = \frac{\partial J}{\partial \theta_2} \dot{\theta}_2 + \frac{\partial J}{\partial \theta_4} \dot{\theta}_4$$

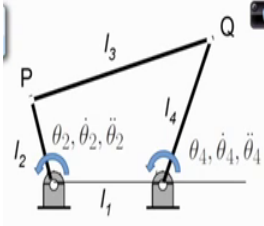

$$\Rightarrow \ddot{\theta}_4 = \left(\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4} J \right) \dot{\theta}_2^2 + J \ddot{\theta}_2$$

Output (pointing to the first term) and Input (pointing to the second term)

So, this is this step I have just shown you, so what we arrive at is the acceleration input output relation. So here I have the input acceleration and on the left I have the output acceleration theta 4 double dot. Now there are few things to note here; this input output acceleration relation is inhomogeneous it is of this form let me write this again in a condensed form. So, here I have written out this in a condensed form, now this relation between theta 4 double dot and theta 2 double dot as you can see is linear. However, there is this extra term; this extra term which is configuration and velocity dependent, such a relation between accelerations will say that it is inhomogeneous.

So, the relation is inhomogeneous. Though the relation is linear the acceleration relation is linear, the acceleration relation input output acceleration relation is linear, but inhomogeneous, the inhomogeneous term is because of the velocity. So, if the velocity is 0 at that instant of time then the acceleration relation becomes homogeneous. So, if the velocity at that instant of time is 0 then the acceleration relation becomes homogeneous, otherwise the acceleration relation is inhomogeneous though linear. There is one more point to be noted, if you require that the output acceleration be 0 if you require the output acceleration to be 0, so let me go to this expression self.

(Refer Slide Time: 20:49)

Analytical velocity relation

$$\dot{\theta}_4 = \left(\frac{l_2}{l_4} \right) \left[\frac{l_4 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_2}{l_2 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_4} \right] \dot{\theta}_2$$

$$\dot{\theta}_4 = J \dot{\theta}_2$$

Time differentiating both sides

$$\ddot{\theta}_4 = \dot{J} \dot{\theta}_2 + J \ddot{\theta}_2$$

$$\dot{J} = \frac{\partial J}{\partial \theta_2} \dot{\theta}_2 + \frac{\partial J}{\partial \theta_4} \dot{\theta}_4$$

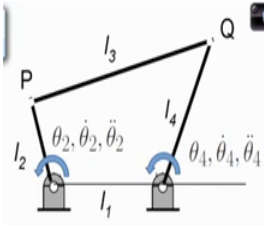

$$\Rightarrow \dot{J} = \left(\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4} J \right) \dot{\theta}_2$$

$$\Rightarrow \ddot{\theta}_4 = \left(\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4} J \right) \dot{\theta}_2^2 + J \ddot{\theta}_2$$

If $\ddot{\theta}_4 = 0$

If I need, if I need the output acceleration to be 0 then I require an input acceleration, so what acceleration do I need so let us do this.

(Refer Slide Time: 21:13)

$$\dot{\theta}_4 = \left(\frac{l_2}{l_4} \right) \left[\frac{l_4 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_2}{l_2 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_4} \right] \dot{\theta}_2$$

$$\dot{\theta}_4 = J \dot{\theta}_2$$

If $\ddot{\theta}_4 = 0$

$$\ddot{\theta}_2 = J^{-1} \left[\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4} J \right] \dot{\theta}_2^2$$

If $\ddot{\theta}_2 = 0$

$$\ddot{\theta}_4 = \left(\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4} J \right) \dot{\theta}_2^2$$

$$\frac{\partial J}{\partial \theta_2} = \frac{l_1 l_2 \sin \theta_4}{l_4} \left[\frac{l_1 \cos \theta_2 + l_4 \cos(\theta_2 - \theta_4) - l_2}{(l_2 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_4)^2} \right]$$

$$\frac{\partial J}{\partial \theta_4} = \frac{l_1 l_2 \sin \theta_2}{l_4} \left[\frac{l_1 \cos \theta_4 + l_2 \cos(\theta_2 - \theta_4) - l_4}{(l_2 \sin(\theta_2 - \theta_4) + l_1 \sin \theta_4)^2} \right]$$

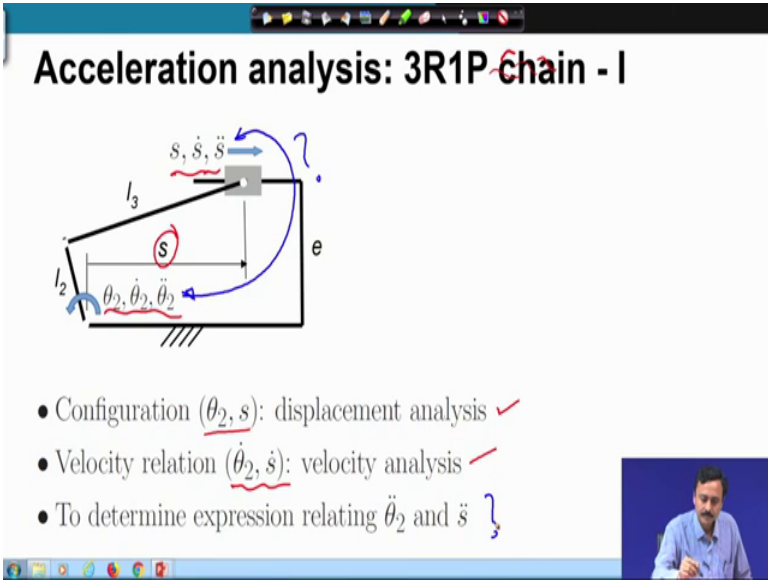

So, here I have written out for you these expressions, now if you look at the expression for del J del theta 2 and del J del theta 4 which is very easy to compute from the expression of J. So, these are given here they look complicated but they can be obtained in a straight forward manner by partial derivative. Now the point that I would like to

mention here is that even if $\ddot{\theta}_4$ is 0 $\ddot{\theta}_2$ in general will not be 0.

So, that will become $J^{-1} \frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial \theta_4}$ into $J \ddot{\theta}_2$ dot square. So, even the $\dot{\theta}_4$ is 0, I will have acceleration at the input I must have acceleration at the input, so that my output does not have any angular acceleration. This is not the case with velocity analysis because that velocity analysis relations velocity relations input output relations are homogeneous, because acceleration input output relations are inhomogeneous that is why even though we desire 0 acceleration at the output we must have acceleration at the input the opposite is also true suppose I do not have acceleration at the input.

Suppose I am driving at a constant speed at the input; I am driving at a constant speed at the input which means that $\ddot{\theta}_2$ is 0 in that case I will have in general I will have acceleration at the output. So, this is the expression of the output acceleration even though I am driving at a constant speed which means input acceleration is 0.

(Refer Slide Time: 24:19)

Acceleration analysis: 3R1P chain - I

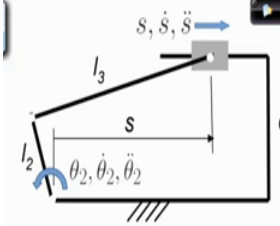

The diagram shows a 3R1P mechanism. A crank of length l_2 is at the bottom left, pivoted to a fixed frame. A connecting rod of length l_3 is attached to the crank at an angle θ_2 . The other end of the connecting rod is attached to a slider block that moves vertically along a guide of length e . The slider block has a vertical displacement s . The diagram is annotated with variables for displacement, velocity, and acceleration: s, \dot{s}, \ddot{s} for the slider and $\theta_2, \dot{\theta}_2, \ddot{\theta}_2$ for the crank. A red circle with 'S' is around the slider displacement, and a blue circle with θ_2 is around the crank angle.

- Configuration (θ_2, s) : displacement analysis ✓
- Velocity relation $(\dot{\theta}_2, \dot{s})$: velocity analysis ✓
- To determine expression relating $\ddot{\theta}_2$ and \ddot{s} }

Now, let us go over to the acceleration analysis of 3R1P chain of type 1. So, here we already have completed the displacement analysis, so which I which means I know the input output displacements, I have completed the velocity analysis which means I can relate $\dot{\theta}_2$ and \dot{s} the output is s and the rates are \dot{s} , \dot{s} dot and \ddot{s} the input is θ_2 and the input rates are $\dot{\theta}_2$ and the acceleration is $\ddot{\theta}_2$

dot. So, what I no need to find out is a relation between this theta 2 double dot and S double dot. So, this is what I need to find out.

(Refer Slide Time: 25:19)

Analytical velocity relation

$$\dot{s} = \left[\frac{l_2(e \cos \theta_2 - s \sin \theta_2)}{s - l_2 \cos \theta_2} \right] \dot{\theta}_2$$

$$\Rightarrow \dot{s} = J \dot{\theta}_2$$

Time differentiating both sides

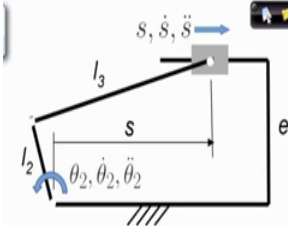

$$\ddot{s} = \dot{J} \dot{\theta}_2 + J \ddot{\theta}_2$$

$$\dot{J} = \frac{\partial J}{\partial \theta_2} \dot{\theta}_2 + \frac{\partial J}{\partial s} \dot{s}$$

$$\Rightarrow \ddot{s} = \left(\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial s} J \right) \dot{\theta}_2^2 + J \ddot{\theta}_2$$

So, here I have written out the analytical velocity relation for the 3R1P chain. Now if you differentiate again with respect to time then you obtain the acceleration relation between S double dot and theta 2 double dot, again we find that it is linear in S double dot and theta 2 double dot though it is inhomogeneous. Here again you time derivate the Jacobean so you have this expression of J dot which you substitute into the expression of S double dot and finally, obtain the input output acceleration relation. So, remember we have started with the analytical velocity relation differentiated that with respect to time and obtain the acceleration relation.

(Refer Slide Time: 26:29)

The diagram shows a slider-crank mechanism. A crank of length l_2 is at an angle θ_2 to the horizontal. A connecting rod of length l_3 is attached to the crank and a slider. The slider moves vertically along a guide. The distance from the crank pivot to the slider is s . The slider's position is also denoted by e . The diagram labels the variables s, \dot{s}, \ddot{s} for the slider's motion and $\theta_2, \dot{\theta}_2, \ddot{\theta}_2$ for the crank's motion.

$$\dot{s} = \left[\frac{l_2(e \cos \theta_2 - s \sin \theta_2)}{s - l_2 \cos \theta_2} \right] \dot{\theta}_2$$

$$\Rightarrow \dot{s} = J \dot{\theta}_2$$

$$\ddot{s} = \left(\frac{\partial J}{\partial \theta_2} + \frac{\partial J}{\partial s} J \right) \dot{\theta}_2^2 + J \ddot{\theta}_2$$

$$\frac{\partial J}{\partial \theta_2} = l_2 s \left[\frac{l_2 - e \sin \theta_2 - s \cos \theta_2}{(s - l_2 \cos \theta_2)^2} \right]$$

$$\frac{\partial J}{\partial s} = l_2 \cos \theta_2 \left[\frac{l_2 \sin \theta_2 - e}{(s - l_2 \cos \theta_2)^2} \right]$$

So, here I have written out for you the expressions of $\frac{\partial J}{\partial \theta_2}$ and $\frac{\partial J}{\partial s}$ which is required in this term of acceleration relation. So, this can be obtained directly from here by taking this partial derivatives.

(Refer Slide Time: 27:05)

Key points

- Analytical input-output acceleration relations
- Input-output acceleration relations are linear but inhomogeneous (except at zero speed)
- Role of inhomogeneous term (speed dependent term)
- Generation of constant output speed, and output acceleration at constant input speed

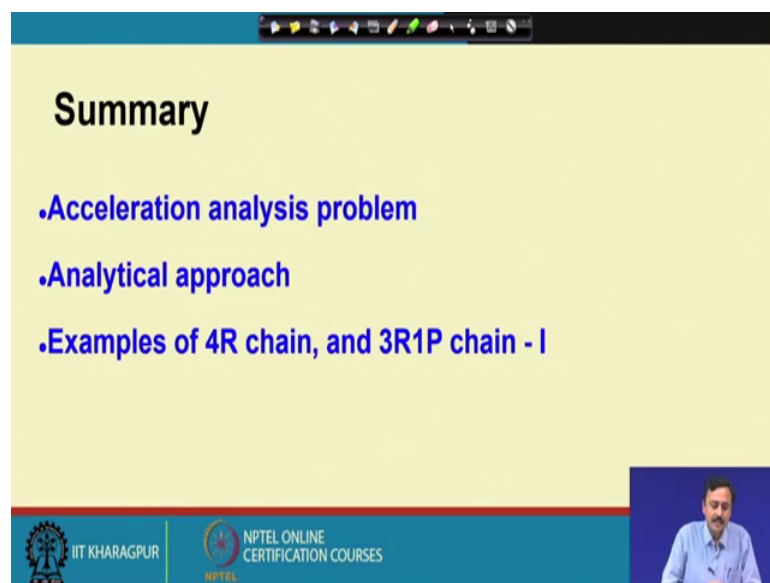

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, what are the key points that we have found we have derived the analytical input output acceleration relations. We are found that the input output acceleration relations are linear though they are inhomogeneous, except at 0 input speed, thirdly we have looked at

the role of the inhomogeneous term which is speed dependent. We have found that if the speed is 0 the input speed is 0 then the acceleration relations become homogeneous.

So, in general the acceleration relations are inhomogeneous. Then we have looked at the constraints that this acceleration relation put on the input output acceleration. So, even though we want to drive the output at constant speed for example, we must have some input acceleration and similarly if you drive the input at a constant speed then you have acceleration at the output.

(Refer Slide Time: 28:15)

The slide is titled "Summary" in bold black font. Below the title, there is a bulleted list of topics in blue font:

- Acceleration analysis problem
- Analytical approach
- Examples of 4R chain, and 3R1P chain - I

At the bottom of the slide, there is a blue footer bar containing the IIT Kharagpur logo and the text "NPTEL ONLINE CERTIFICATION COURSES". In the bottom right corner, there is a small video inset showing a man in a blue shirt, presumably the lecturer.

So, to summarize we are looked at the acceleration analysis problem, we have taken the analytical approach and we have looked at 2 examples the 4R kinematics chain and the 3R1P kinematic chain of type 1. So, with that I close this lecture.
