Lecture – 25
Linear stability analysis – Planar Liquid Sheet instability -2

Welcome back. We were looking at the linear instability analysis of a plain liquid sheet. This is essentially if you imagine a liquid sheet that is flat, but has a finite thickness which is about we called it $2h$ exiting into and otherwise quiescent atmosphere. We look at the density of the liquid sheet was ρ_1 and it was moving with the velocity U_1 . The density of the air outside, if you want to call it the fluid outside was ρ_2 on the top ρ_3 on the bottom and U_2 and U_3 . But essentially ρ_2 and ρ_3 we will set equal to each other. Say it is exactly the case of a plain liquid sheet exiting into atmosphere.

And one point we have to understand in all this linear instability analysis is that we are looking at the stability of an infinite liquid sheet. There is no substring as a nozzle from which the liquid sheet is exiting. Now you can do an instability analysis of what is called a semi infinite liquid sheet where you show the presence of a nozzle and then say you cannot have the possibility of disturbances upstream of that and you can only have the possibility of disturbances downstream of the nozzle.

But, we are not going to focus our attention. We are only going to focus our attention today on the linear instability analysis of a plain liquid sheet; exiting that of an infinite plain liquid sheet.

(Refer Slide Time: 01:54)

Let us look at the schematic that we have, like I said the sheet is of thickness $2h$, the density of the fluid is ρ_1 and it is moving with the velocity U_1 , uniform in the entire sheet and ρ_3 we are going to set equal to ρ_2 .

(Refer Slide Time: 02:30)

We went through the process of writing the Euler's equations for both the fluids, and then going through the perturbation process for the 2 fluids, and we came as far as calculating the pressure field in the fluid above and the fluid below.

(Refer Slide Time: 02:40)

$$p_2(x, y) = C_{12} e^{-ky} e^{ikx} e^{\omega t} = C_{12} e^{-ky(\omega t + ikx)}$$

$$p_3(x, y) = C_{13} e^{ky} e^{ikx} e^{\omega t} = C_{13} e^{ky(\omega t + ikx)}$$

Take $\frac{\partial}{\partial x}(\text{eq.3}) + \frac{\partial}{\partial y}(\text{eq.4}) \Rightarrow$

$$\frac{\partial}{\partial t} \left(\frac{\partial u_1}{\partial x} + \frac{\partial v_1}{\partial y} \right) + U_1 \frac{\partial^2 u_1}{\partial x^2} = -\frac{1}{\rho_1} \left[\frac{\partial^2 p_1}{\partial x^2} + \frac{\partial^2 p_1}{\partial y^2} \right]$$

The pressure field in the fluid above p 2 is given by this expression $C_{12} e^{-ky} e^{ikx} e^{\omega t}$. I can write it slightly more compactly in the form that we are otherwise use to which is likewise p 3, and then this is essentially the fluid above and the fluid below p 2 and p 3. As far as the liquid sheet itself is concerned we went through the process of eliminating one of the variables.

(Refer Slide Time: 04:05)

$$(u_1, v_1, p_1) = [u_1''(y); v_1''(y); p_1''(y)] e^{(ikx + \omega t)}$$

$$(\omega + ikU_1) u_1'' = -ik p_1'' \quad \text{--- (9)}$$

$$\omega v_1'' = -\frac{1}{\rho_1} \frac{dp_1''}{dy} \quad \text{--- (10)}$$

And using the normal mode assumption, we got these equations 9 10 and 11. I can multiply equation 9 by ik and take one over $\omega d dy$ of equation 10.

(Refer Slide Time: 04:24)

$$ik u_1'' + \frac{d v_1''}{dy} = 0 \quad \text{--- (11)}$$

$$\frac{(ik) \times (9)}{(\omega + ik U_1)} + \frac{1}{\omega} \frac{d}{dy} (10)$$

eg. (9)

$$u_1'' = -\frac{ik}{\rho_1 (\omega + ik U_1)} p_1''$$

$$ik u_1'' = \frac{k^2}{\rho_1 (\omega + ik U_1)} p_1''$$

You will see why I am doing this; it is essentially to get to the form that is in equation 11; if I divide this by $\omega + ik U_1$ and multiply by ik .

Let me do that equation 9 first, becomes $U_1'' = -1 / (\rho_1 (\omega + ik U_1)) p_1''$. So, $ik U_1''$, you have ik times ik that is minus k^2 , but with the other negative sign is this becomes k^2 / ρ_1 , I call this equation 12.

(Refer Slide Time: 06:03)

eq. (10)

$$\omega v_1'' = -\frac{1}{\rho_1} \frac{d p_1''}{dy}$$

$$\frac{d v_1''}{dy} = -\frac{1}{\rho_1 \omega} \frac{d^2 p_1''}{dy^2} \quad \text{--- (13)}$$

Adding (12) to (13),

Now, equation 10 is ωv_1 , if I take derivative of this with respect to y , I call this equation 13.

(Refer Slide Time: 07:22)

The image shows a handwritten derivation on a digital whiteboard. At the top, a red arrow points to the text "0 (eq. 11)". Below this, the equation $ik u_1'' + \frac{dv_1''}{dy} = -\frac{1}{\rho_1 \omega} \frac{d^2 p_1''}{dy^2} + \frac{k^2}{\rho_1 (\omega + ik U_1)} p_1''$ is written. Below this, it says "Using (11)", followed by the simplified equation $\frac{d^2 p_1''}{dy^2} - \frac{\rho_1 k^2 \omega}{\rho_1 (\omega + ik U_1)} p_1'' = 0$.

Now using 11, we will find that this right hand side is 0 because of equation 11. What we have, I will write this in a slightly different way, but still recognizable.

(Refer Slide Time: 09:32)

The image shows a handwritten derivation on a digital whiteboard. It starts with "Eq. (14) is of the form," followed by the equation $\frac{d^2 p_1''}{dy^2} - \lambda^2 p_1'' = 0$; $\lambda^2 = \frac{k^2 \omega}{(\omega + ik U_1)}$. Below this, the solution is given as $p_1''(y) = C_{21} \sinh(\lambda y) + C_{23} \cosh(\lambda y)$. At the bottom, it says " C_{12}, C_{13}, C_{21} and C_{23} are as yet".

Essentially I have now an equation for p_1 double prime. This is of the form equation 14 where λ^2 equals $k^2 \omega$ over $\omega + ik U_1$. The ρ_1 cancels out. The solution to this; I call this 21 and 23 just for consistency of

nomenclature. I have this C 21 and C 23 are as yet; undetermined, and likewise you have these 2 constants in the pressures C 12 and C 13.

I have C 12, C 13, C 21, and C 23. Now, I am going to go back to the schematic that we had the plain liquid sheet.

(Refer Slide Time: 12:52)

I will just copy this whole thing; this is my unperturbed configuration. If I look at the perturbations on this, so I can have 2 kinds of perturbations on this and this is the fundamental difference between a plain liquid sheet and all of the analysis we had before. This problem has 2 interfaces as suppose to one that is always be in the case.

What do we do with the 2 interfaces? I will call the above the interface on top as eta top and the one on the bottom as eta bottom. If I write the form of eta t and eta b, so essentially $y = \eta_t(x,t)$ is the equation determining of the top interface and $y = \eta_b(x,t)$ is the equation determining of the bottom interface.

(Refer Slide Time: 14:34)

$y = \eta_b(x, t)$ is the eqn. of the bottom interface
 $\eta_t(x, t) = \eta_{0t} e^{(\omega t + ikx)}$
 $\eta_b(x, t) = \eta_{0b} e^{(\omega t + ikx)}$
 Boundary conditions, @ t - interface

Now, because of the linearity in the problem this clearly has a functional form that is similar to the functional form that already has occurred in the pressures. I will call this $\eta_{0t} e^{\omega t + ikx}$. This is coming from the normal mode assumption.

Now that we know the interface shape, we can write down the boundary conditions. The boundary conditions at the t interface which is the top interface.

(Refer Slide Time: 16:33)

Kinematic boundary condition,

$$v_2' \Big|_{y=h} = \frac{\partial \eta_t}{\partial t} \quad ; \quad v_1' \Big|_{y=h} = \frac{\partial \eta_t}{\partial t} + U_1 \frac{\partial \eta_t}{\partial x}$$
 (15) (16)
 Dy

The first one like we have always written is the kinematic boundary condition. I will write it from the direction of fluid 2 and from the direction of fluid 1. From the direction

of fluid 2, what I know is that v_2' , which is the y direction velocity in fluid 2 has to equal, the partial derivative of η with respect to t . This evaluated at y equal to h has to equal this. From the fluid 1 point of view v_1' at y equal to h has to equal the partial derivative of η with respect to t plus U_1 partial derivative of η with respect to x . And all these derivatives evaluated at the unperturbed free surface.

We have discussed this at least twice during the course of the previous lectures, but I reiterate one more point of you sort to say that v_1' and v_2' in these two. In this equation are the Eulerian velocities at the interface whereas if the right hand side of each of these 2 equations is the same velocity at the same point written from a Lagrangian point of view. If I was a material particle on the interface and I am governed by the equation $\frac{d\eta}{dt}$ which means the rate of motion that I am subjected to is fixed therefore, the material velocity at the interface say either in fluid 1 or fluid 2 has to equal the corresponding velocity coming from the Eulerian description that is the physical essence of the kinematic boundary condition.

(Refer Slide Time: 19:29)

Dynamic boundary condition

$$p_2 - p_1 = \sigma k$$

$$y - \eta_t(x, t) = 0$$

$$k = \frac{-\frac{d^2y}{dx^2}}{\left(1 + \left(\frac{dy}{dx}\right)^2\right)^{3/2}}$$

Now, if I write down the dynamic boundary conditions, I will call these, I have 2 kinematic boundary conditions at the top interface. How many dynamic boundary conditions do I expect to have? It is only going to be one because what that, what the dynamic boundary condition amounts to is essentially a force balance on a tiny element. If I take an element of fluid just like that and write down the force balance on that

element of fluid, that element of fluid is chosen to span both fluids, but of an infinitesimal thickness. Its own mass is nearly 0, which means the pressures acting on both sides and the net result and forces should all be balanced out. If I say force equals mass times acceleration the mass of the element itself is small, then you are essentially looking at something that is where the forces are all equal since static equilibrium that is what we call the dynamic boundary condition.

With that, if I write down the pressure in fluid 2 minus the pressure in fluid 1 equals σ times κ , we have already gone through this process of identifying what κ would be. If I know y minus η at x is equal to 0 is the equation of the surface, κ is given by this minus $d^2 y / dx^2$ divided by $1 + (dy/dx)^2$ raised to the power 3/2.

(Refer Slide Time: 22:06)

$$\begin{aligned} \kappa &= \frac{+k^2 \eta_0 e^{(\omega t + ikx)}}{\left[1 + ik \eta_0 e^{(\omega t + ikx)}\right]^{3/2}} \\ &= k^2 \eta_0 e^{(\omega t + ikx)} \left[1 - \frac{3}{2} \eta_0 (ik) e^{2(\omega t + ikx)} + \dots\right] \\ &= k^2 \eta_0 e^{(\omega t + ikx)} \quad \text{where the bracketed term is } \mathcal{O}(\epsilon^2) \end{aligned}$$

If I simplify that knowing what the form of η is, this is $\eta_0 e^{\omega t + ikx}$. This if I take derivative twice, one derivative gives me ik times. This is another derivative gives me ik times ik which is minus k^2 . This becomes plus k^2 $\eta_0 e^{\omega t + ikx}$ is essentially ik using the Taylor series expansion that we had.

I can clearly see that the minus 3/2 this term here is order ϵ^2 . This simply becomes, this is the formula for the curvature.

(Refer Slide Time: 24:59)

The image shows a digital whiteboard with handwritten mathematical equations. The equations are as follows:

$$p_2 - p_1 \Big|_{y=h} = \sigma k^2 \eta_0 e^{(\omega t + i k x)}$$

$$C_{12} e^{-k h} e^{(\omega t + i k x)} - [C_{21} \sinh(k h) + C_{23} \cosh(k h)] e^{(\omega t + i k x)} = \sigma k^2 \eta_0 e^{(\omega t + i k x)} \quad (17)$$

$$C_{12} e^{-k h} - C_{21} \sinh(k h) - C_{23} \cosh(k h) = \sigma k^2 \eta_0$$

If I substitute that in the dynamic boundary condition, I have p_2 minus p_1 evaluated at y equal to h is equal to $\sigma k^2 \eta_0 e^{(\omega t + i k x)}$, we will actually do this just to sort of show, what it looks like p_2 is known really speaking these are the prime quantities p_2 prime and p_1 prime because the mean pressure condition was where everything was at the same pressure.

I can go get the forms for p_2 and p_1 p_2 is given by this $C_{12} e^{(\omega t + i k x)}$ minus $k h$ times $e^{(\omega t + i k x)}$. This is $C_{12} e^{(\omega t + i k x)}$ minus $k h$ times $e^{(\omega t + i k x)}$. This is p_2 prime at y equal to h p_1 prime at y equal to h has these 2 C_{21} and C_{23} , but this is p_1 double prime. We just have to multiply this by $e^{(\omega t + i k x)}$. This is simply the right hand; the left hand side of this equation. The right hand side says $\sigma k^2 \eta_0 e^{(\omega t + i k x)}$.

From here I have one equation that $C_{12} e^{-k h}$ minus $C_{21} \sinh(k h)$ sorry C_{12} minus $C_{23} \cosh(k h)$ equals $\sigma k^2 \eta_0$ likewise. I have this is my equation 17 which is, I have 15 16 and 17 as the 3 boundary conditions at the t interface.

(Refer Slide Time: 29:21)

Boundary conditions at b-interface,

$$v_3' \Big|_{y=-h} = \frac{\partial \eta_b}{\partial t} \quad ; \quad v_2' \Big|_{y=-h} = \frac{\partial \eta_b}{\partial t} + U_1 \frac{\partial \eta_b}{\partial x}$$

(18) (19)

$$\frac{\partial v_3'}{\partial t} = -\frac{1}{\rho_2} \frac{\partial p_3'}{\partial y} \quad ; \quad p_3' = C_{13} e^{k_y (\omega t + i k x)}$$

Likewise, if I write the boundary conditions at the bottom interface, I will have the following first of all v_3 , v_3 prime at y equal to minus h is equal to $d \eta_b / dt$ and v_2 prime at y equal to minus h equals $d \eta_b / dt$ plus $U_1 d \eta_b / dx$ these are the kinematic boundary conditions at 18 19.

Just as we did the dynamic boundary condition part with the top interface, I am going to implement this in some detail with the bottom interface. If I go back, I know what p_3 double prime looks like, p_3 x comma y comma t is given by this whole thing, If I evaluate, from this p_3 , I can go to equation 7 or as the equation, that is look like equation 7 essentially because the fluid on top and bottom 1 and 2 are essentially the same the equation for the v velocity in fluid 3 will look exactly like equation 7 with the subscript 2 replaced by 3.

I know $dv_3 \text{ prime} / dt$ equals minus 1 over ρ_2 because ρ_2 and ρ_3 are the same and knowing p_3 prime is $C_{13} e^{k_y (\omega t + i k x)}$.

(Refer Slide Time: 33:18)

$$\omega v_3' = -\frac{1}{\rho_2} C_{13} k e^{k y} \Rightarrow v_3' = -\frac{1}{\rho_2 \omega} C_{13} k e^{k y} e^{(\omega t + i k x)}$$

Sub, v_3' in (18),

$$-\frac{1}{\rho_2 \omega} C_{13} k e^{-k h} e^{(\omega t + i k x)} = \omega \eta_{0b} e^{(\omega t + i k x)}$$

$$-\frac{1}{\rho_2 \omega} C_{13} k e^{-k h} = \omega \eta_{0b}$$

What we find is that knowing v_3' is also of the normal mode form. From here, I find $\omega v_3'$ double prime is minus 1 over ρ_2 times $C_{13} k$ times $e^{k y}$. This is the functional form, this is equation it gives you the functional form for v_3' double prime.

If I use, if I substitute that in the boundary condition 18, what we have at for 18 is v_3' prime evaluated at y equal to minus h equals $d \eta_b / dt$, the partial derivative of η_b with respect to t . If I evaluate v_3' prime at y equal to h , I have minus 1 over $\rho_2 \omega$ $C_{13} k e^{k y}$ plus k minus $k h$ because y equals minus h $e^{k y}$ equals $\omega \eta_{0b} e^{k y}$ note is how the exponentials cancel out in pretty much all these equations what we are left with is.

So, this is 20, but comes from 18, I can likewise go through and do the same thing for 19, I am just showing you, how you can take the solution that we have for the pressure and find the y direction velocity and use the kinematic boundary condition to come up with the expression relating the unknown constants and η_{0s} , η_{0t} and η_{0b} .

(Refer Slide Time: 37:23)

Dynamic boundary condition @ b-int.

$$p_2 - p_3 \Big|_{y=-h} = \sigma k$$

$$k = k^2 \eta_{0b} e^{(\omega t + i k x)} \quad (2)$$

Now the last part is the dynamic boundary condition at the b interface and what we have here is $p_2 - p_3$ equals σk evaluated at y equal to minus h . You can find k to be the same keys k squared η_{0b} e power ωt plus $i k x$ up to order epsilon.

(Refer Slide Time: 38:47)

$$[C_{12}, C_{13}, C_{21}, C_{23}, \eta_{0b}, \eta_{0t}]^T = \{x\}$$

SIX boundary conditions,

4 K.B.C and 2 D.B.C's

$$[A]\{x\} = 0$$

Let us quickly take stock, what are the unknown constants that we are yet to find? We have C_{12} , C_{13} , C_{21} , C_{23} η_{0b} and η_{0t} we have 6 boundary conditions, basically 4 kinematic boundary conditions and 2 dynamic boundary conditions. In total, when you go through this process though it looks like a nice consistence Eigen value problem.

Now, minds you that all these boundary conditions yield only homogeneous equations if we look at equation 20 as an example, C 13 is my unknown constant $\eta_0 v$ is one of the unknowns in the list that we had just here under likewise, everyone of our equations would be an like for example, here C 12, C 21, C 23, and $\eta_0 t$. Every one of these equations would yield you a homogenous equation, every one of the boundary conditions would yield a homogenous equation in these 6 unknowns that are shown here.

But the problem is that you will find that when you go through this process, the rank of the matrix is less than even 5. Essentially you have a 6 by 6 matrix. If I write this out in the form of $\mathbf{A} \mathbf{x} = \mathbf{0}$, where $\mathbf{x}$ vector is basically that I can, write these 6 equations in this form, what we will find is that we, in order for me to set the determinant to 0 i do need one more condition the because some of the equations give you the same, they are essentially the same equation.

(Refer Slide Time: 42:34)

$\det[A] = 0$ is characteristic equation.

$\frac{\eta_{0b}}{\eta_{0t}} = \pm 1$

$\lambda = \frac{2\pi}{k}$

$\omega = f(k)$ for $\frac{\eta_{0b}}{\eta_{0t}} = 1$ {Sinuous mode}

$\omega = g(k)$ for $\frac{\eta_{0b}}{\eta_{0t}} = -1$ {Varicose mode}

You will not be able to eliminate all these equations to get you to the characteristic equation. The condition that is used is basically assigning a value to this ratio. Now let us quickly look at what this ratio means. If I take 2 menisci and if one of this menisci's has a perturbation of that form, I have 2 possibilities for the bottom 1, it is in phase or exactly out of phase.

This number can either be plus or minus 1. Depending on whether you choose this to be equal to plus one or whether you choose that equal to minus 1, you get 2 different

characteristic equations arising from setting this determinant equal to 0. These are of this form, but determinant of a equal to 0 is the characteristic equation. Whether you choose this ratio to be equal to plus 1 or whether you choose it equal to minus 1, gives you 2 separate characteristic equations that is essentially if you go back, what is the characteristic equation characteristic equation is $\sum f$ of k . So, you have one equation for η_b over η_t equal to one which are called sinuous perturbations sinuous mode would be a better way to say and you get another equation this is call the varicose mode.

For a given wavelength or for a given wave number for a given wave number, I can get one growth rate, if the disturbance was in the sinuous mode and I can get another growth rate, if the disturbance was in the varicose mode. For a given flow situation, I need to know what disturbance that I am looking at. I can plot my dispersion diagram which is ω versus k . I want to ultimately identify the value of k for which ω is a maximum and for me to e get to that condition; I need to know which mode, it is that I am looking at.

Typically, what you could do is that you could plot a dispersion diagram for both the sinuous mode and the varicose mode and choose the one k that has the maximum growth rate of all the modes possible of both the sinuous and the varicose modes. In fact, this is kind of nice if you go back and look at what this actually physically means the, if I assume the sheet is of the, if I assume the sheets to be composed of parallel menisci, initially in the unperturbed condition the sinuous mode says that both of them are in phase which is like saying that the sheet is going to. If I look at the top meniscus in the bottom meniscus as being the top and bottom surfaces of my palm essentially they are both in phase sort of like that.

This is like a flag flapping in a breeze for example, would be the case of a Para of a sinuous mode except for a rigid object you cannot have a varicose mode, but since you have a you are dealing with the liquid sheet the liquid sheet could go in to a mode where it thickens and thin at one point and thins at another point completely symmetric about the half way axis about the x equal to about the y equal to 0 position. There are situations where we see that a sheet thickens and thins within the varicose mode there are situations where the sheet is more of a flapping nature.

Depending on the flow condition you may get one kind of break up or the other now if you go back and look at the analysis that we have that we have performed there is nothing in this analysis that says that the liquid sheet that you have a liquid sheet exiting into air. They are just fluids of some densities I could have a gaseous sheet. Like a sheet of gas, that is let us say entering an otherwise quiescent liquid now you can imagine, how if I did that the varicose mode would essentially mean bubbles forming the menisci sort of being anti symmetric to each other or menisci being mirror images about the y equal to 0 axis would among to sort of like a bubble becoming trapped.

If you did this analysis, you would find that the situation where ρ_2 is less than ρ_1 and ρ_1 is less than ρ_2 and ρ_3 would give you the varicose mode showing the dominant behavior whereas, if you had a liquid sheet exiting into air generally speaking you would find a sinuous mode dominantly.

(Refer Slide Time: 49:21)

The dispersion relation of a two-dimensional inviscid liquid sheet is, (SINUSOIDAL)

$$\underbrace{(\rho_l)}_{=\rho_1} (\underbrace{\omega + ikU_o}_{=U_1})^2 \tanh(k\alpha) + \underbrace{(\rho_g)}_{=\rho_2} \omega^2 + \sigma k^3 = 0$$

ρ_l = Density of the liquid sheet
 ρ_g = Density of the gas medium
 U_o = Velocity of the liquid sheet
 σ = Surface tension of the liquid sheet
 k = Wave number
 α = Thickness of the liquid sheet

 Ibrahim and E.T. Akpan, Liquid sheet instability, Acta Mechanica 131: 153-167, 1998

Let us look at some results. If I completed this analysis, what I will get is a dispersion relation that looks like this. With this alpha being equal to $2h$ in our analysis this is from this paper by Ibrahim and Akpan from Acta Mechanica. This U_0 in their nomenclature is our U_2 our sorry our U_1 . The ρ_{liquid} is what we called ρ_1 and ρ_g is what we call ρ_2 .

So, this is essentially a quadratic in omega. So that I can solve just like the previous situation, I can write omega is minus 10 hyperbolic or essentially I can write the

dispersion relation in closed form where I will get 2 roots for a given value of k . Now, this is for a sinuous mode. Somewhere along you will see if you go back to this reference they would have assume that η_{0t} or η_{0b} over η_{0t} is equal to 1.

(Refer Slide Time: 51:22)

The dispersion relation of a two-dimensional viscous liquid sheet is,

$$\left[\rho_l (\omega + ikU_0) + 2\mu_l k^2 \right] \left[\nu_l (k^2 + s^2) \right] \tanh(k\alpha) - 4\mu_l \nu_l k^3 s \tanh(s\alpha) + \rho_g \omega^2 + \sigma k^3 = 0,$$

ρ_l = Density of the liquid sheet
 ρ_g = Density of the gas medium
 μ_l = Dynamic viscosity of the liquid sheet
 ν_l = Kinematic viscosity of the liquid sheet
 U_0 = Velocity of the liquid sheet
 σ = Surface tension of the liquid sheet
 k = Wave number
 α = Thickness of the liquid sheet
 s depends on k , ω , ν_l and U_0 .

 Jasti and R. S. Tankin. On the temporal instability of a two-dimensional viscous liquid sheet. Journal of Fluid Mechanics, 226:425-443, 1991.

Now, if I look at the results from; if I look at an extension of this now, all over thus far we have only looked at in viscid analysis. At the beginning of the next class we will start off with including the effect of viscosity; liquid viscosity and see what we find.
