Lecture - 20
Electrokinetics and Magnetophoresis

Okay we have been talking about dielectrophoresis where you know we manipulate particles inside microchannels that are dielectric in nature and we subject the particles to inhomogeneous electric field. Let us continue our discussion on magnetophoresis. Now magnetophoresis is analogous to dielectrophoresis, but here we are talking about particles that are magnetizable okay.

So magnetophoresis is the manipulation of magnetizable particles in presence of inhomogeneous magnetic field okay.

(Refer Slide Time: 00:55)

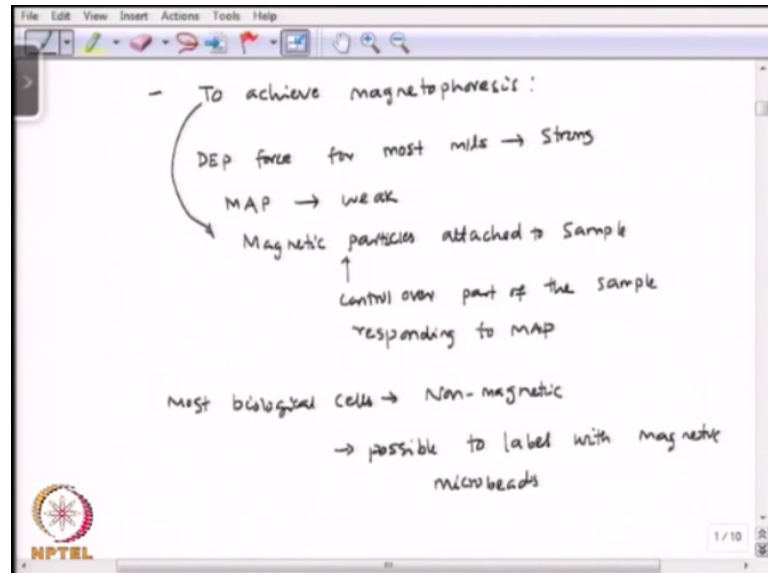

So magnetophoresis is analogous to dielectrophoresis and here we talk about particles that are magnetizable so magnetophoresis means manipulation of magnetizable particles in an external inhomogeneous magnetic field and magnetic field is denoted by symbol H okay. Now the dielectric response of most of the biological materials are very strong okay, but the magnetic response of the biological materials are very weak okay.

So in order to achieve good you know magnetic or magnetophoresis in microchannels what we do is we tag or label these biological particles with the magnetic particles okay. So the

magnetophoresis can be enhanced by tagging biological particles with magnetic particles so in that way we can selectively tag specific population of biological objects with certain types of magnetic particles and we can separate them using magnetophoresis.

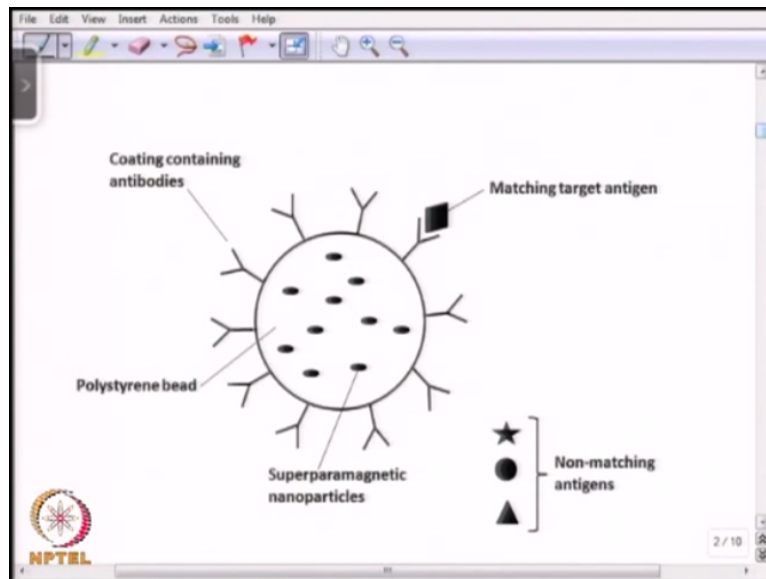

(Refer Slide Time: 03:23)

So you know in magnetophoresis to achieve magnetophoresis you know the DEP force for most materials it is strong, but the magnetophoretic force or we call it MAP magnetophoretic force is weak okay. So to achieve magnetophoresis what you do is magnetic particles attached to sample okay so in that way we can obtain control over you know part of the sample responding to MAP responding to magnetophoresis.

So as I said most biological cells are non-magnetic, so it is possible to label with magnetic microbeads okay.

(Refer Slide Time: 05:34)

So you know here we see an example so this is the polystyrene bead okay and which is not magnetic and here this polystyrene bead is made magnetic by having these super paramagnetic nanoparticles inside okay. The super paramagnetic means you know these particles will go back to their non-magnetic nature when the magnetic field is taken out that is called superparamagnetic okay.

(Refer Slide Time: 06:23)

So by superparamagnetic we mean that the average magnetic moment returns to 0 when external magnetic field is removed okay. So when we take out when we have external magnetic field present these nanoparticles will behave as if they are magnetic and when we take out the magnetic field they will become non-magnetic okay so that is called superparamagnetic nanoparticles.

(Refer Slide Time: 07:28)

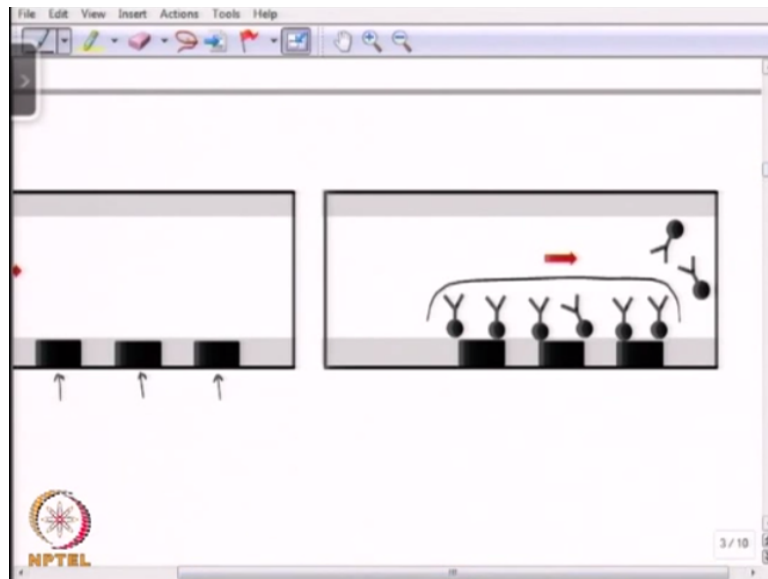

So they are present inside this polystyrene bead so the bead acts as a magnetic particle okay. On the bead, we have a coating of antibodies okay and you know in a sample we may have various different types of antigens and only the matching target antigen will bind to these antibodies okay so these are the antibodies coated onto this magnetic bead and only the matching target antigen will be bound to these antibodies.

And there will be several non-matching antigens that may also be present in the sample which will not bind to the antibodies. So this is one approach how you can you know extract different molecules from the sample using the magnetophoresis method okay so you know it is possible to do magnetophoresis in microfluidic channels where we can have you know these paramagnetic microbeads you know adhering to the wall because of an external magnet.

And you know once these magnetic microbeads with antibodies coated are immobilized onto the wall we can flow the sample and the target antigen can be bound specifically to that antibody, which is attached to the magnetic bead.

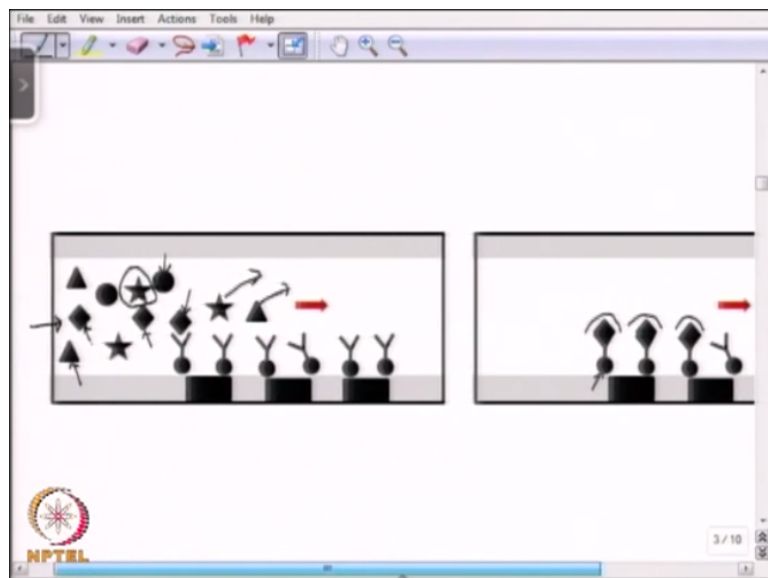

(Refer Slide Time: 09:07)

So this is 1 such case shown here. What we see here? This is a microchannel okay so this is the width of the microchannel and we have these magnets present these 3 black rectangles that we see is there you know magnets and we flow these magnetic bead attached to antibody okay what do we see here is this is the magnetic bead attached to the antibody, which is specific to a particular antigen through the microchannel.

And you know when you do so what we see here because of the influence of the external magnet here these beads get attached to the magnet okay. So they get attached to the channel wall here as you see here okay. So these beads are attached to the channel wall okay.

(Refer Slide Time: 10:09)

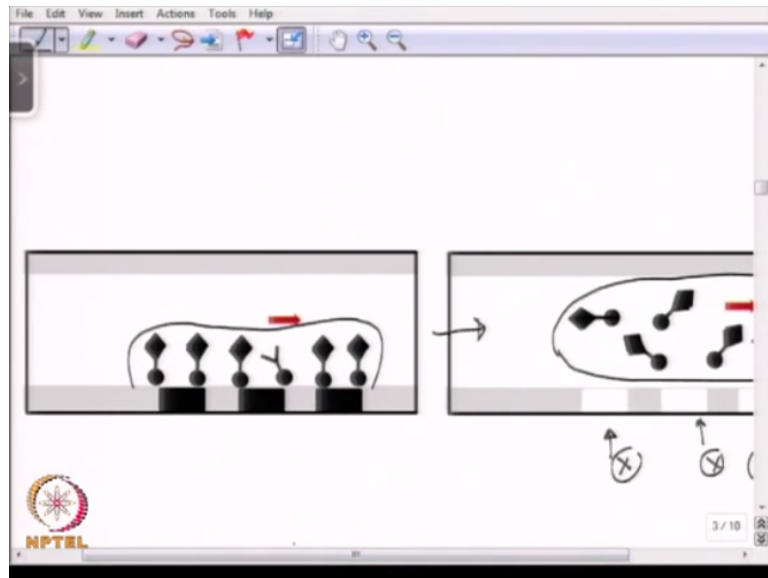

What we do next is you know as you see here we infuse the sample that is having different types of antigens okay and when we do that you know the target antigen, which is specific to

the antibody binds okay so this is the target antigen okay and these target antigens bind to the antibodies okay whereas the other antigens okay this, this and this they are not target antigens so they just flow out allowing the channel okay.

So what we end up getting is you know this magnetic bead attached to the antibodies you know these antigens come and bind to the specific antibodies okay.

(Refer Slide Time: 11:18)

Now once we do that next what we do is you know anything that is not bound is removed okay so we have only magnetic bead with antibody and attached to the target antigen and then we may be interested in these antigen antibodies to do further biology so to do that we can take off the magnetic field so here the magnet is removed and when you do that and we subject this bead antigen to a flow, these antigens and the antibodies can be collected okay.

Because there is no magnetic field, here we have taken off the magnetic field, these antibodies, antigens and the magnetic bead can be released and they can be collected okay. So this is an example of the applications of magnetophoresis what you can use to you know capture antigens and how to release them to collect to process for the biology okay. So let us look at the basics of magnetostatics.

By magnetostatics we mean that the current that we are dealing with is not changing with time so it is invariant with time, so under that assumption will look at the magnetostatic limit of the Maxwell's equation okay.

(Refer Slide Time: 12:54)

Magnetostatics:

- Magnetostatic part of Maxwell's eqn.
- Assume: stationary current density & time derivatives neglected

Magnetic induction

$$\nabla \cdot \mathbf{B} = 0$$

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{J}_{\text{total}} = \mu_0 \mathbf{J}_{\text{ext}} + \mu_0 \mathbf{J}_{\text{mag}}$$

4/10

So let us look at magnetostatics okay so we basically look at the magnetostatic part of the Maxwell's equation okay and here we assume that the stationary current density and any time derivative are neglected okay. So under that assumption we can write the Maxwell's equation for magnetostatic in this way so we will have 2 important equations. The first one is the divergence of magnetic induction is 0 okay.

Where B is magnetic induction okay and the second equation will be $\nabla \times \mathbf{B} = \mu_0 \mathbf{J}_{\text{total}}$, which is the magnetic permeability of vacuum okay $\mu_0 \times \text{total current density}$, which will be $= \mu_0 \text{ external current density} + \mu_0 \text{ the current density bound to the magnetic field}$ okay so we have these 2 equations and here we have B is the magnetic induction we already defined here.

(Refer Slide Time: 15:08)

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{J}_{\text{total}} = \mu_0 \mathbf{J}_{\text{ext}} + \mu_0 \mathbf{J}_{\text{mag}}$$

$\mu_0 = \text{mag. permeability of vacuum} = 4\pi \times 10^{-7} \text{ H/m}$

$\mathbf{J}_{\text{tot}} = \text{Total current density}$

$\mathbf{J}_{\text{ext}} = \text{External current density (running in a conductor)}$

$\mathbf{J}_{\text{mag}} = \text{Current density bound to magnetic material}$
↙ equivalent to polarization charge density in DEP

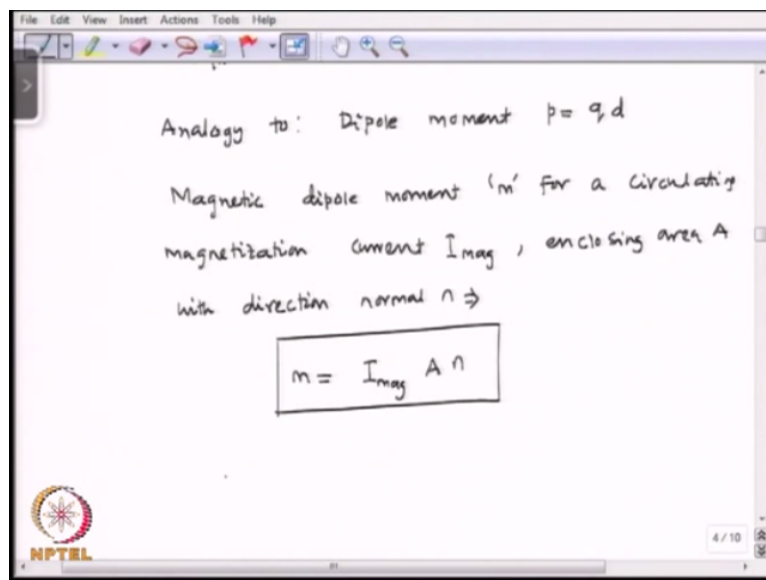

Analogy to: Dipole moment

4/10

And μ_0 is the magnetic permeability of vacuum $= 4\pi \times 10^{-7}$ Henry per meter. So this is magnetic permeability of vacuum μ_0 . J total is the total current density and J external is the external current density for example running in a conductor okay and the J magnetic is the current density bound to the magnetic material and this is equivalent to the polarization charge that we talked in DEP okay.

So this is equivalent to the polarization charge density in DEP okay. Now if you do an analogy to the dipole moment so we do analogy to dipole moment so the electrical dipole moment is charged into the separation distance between the 2 opposite charges, so we can write the electrical dipole moment p as $q \cdot d$. Similarly, we can define something called magnetic dipole moment okay.

(Refer Slide Time: 18:04)

So similar to the electric dipole moment $p = q \cdot d$ we can write something called magnetic dipole moment m for a circulating magnetization current I_{mag} and then closing area A with direction normal \hat{n} so you can write this expression as $m = I_{\text{mag}} A \hat{n}$ so this is along \hat{n} okay.

(Refer Slide Time: 19:21)

- Magnetization M

$$M = \lim_{\text{Vol}(\Omega^* \rightarrow 0)} \left[\frac{1}{\text{Vol}(\Omega^*)} \int_{\Omega^*} d\mathbf{r} \, m(\mathbf{r}_0 + \mathbf{r}) \right]$$

location of mag. dipole.

- ' M ' is related to J_{mag} :

$$J_{\text{mag}} = \nabla \times M$$

$\rho_{\text{pol}} = -\nabla \cdot \mathbf{P}$

4/10

Similarly, we have a term polarization in electric field we can write a term magnetization. So magnetization is equivalent to polarization in dielectrophoresis okay. So you can write magnetization M as limit the volume Ω^* tending to 0 $1/\text{volume } \Omega^*$ integration over Ω^* $d\mathbf{r} \cdot m(\mathbf{r}_0 + \mathbf{r})$ okay. So this is the expression for the magnetization and \mathbf{r}_0 is the location of the magnetic dipole okay.

So location of the magnetic dipole okay and \mathbf{r} is at any point okay. So with that we can relate magnetization to the magnetic current density so the magnetization M is related to the magnetization current density. We can write $J_{\text{mag}} = \nabla \times M$ okay. So this is analogous to we have electrical charge density the polarization charge density $= -\nabla \cdot \mathbf{P}$ okay. So this is polarization okay so equivalent to this in magnetophoresis we have magnetic current density as $\nabla \times M$ okay.

(Refer Slide Time: 21:54)

$D = \epsilon_0 E + P \rightarrow \text{electrostatic}$
 Magnetic field: $H = \frac{1}{\mu_0} B - M$
 Take divergence of H & use $\nabla \cdot B = 0$
 $\rightarrow \nabla \cdot H = -\nabla \cdot M$

Now we have the electrical displacement = $\epsilon_0 E$ + the polarization okay, this is in the electrostatic. In magnetostatic, we have the magnetic field can be written as so H is the magnetic field is $1/\mu_0 B - M$ so H is the magnetic field, B is the magnetic induction and M is the magnetization. So now if we take divergence of you know the magnetic field and we take divergence of H and we use that the divergence of the magnetic induction is 0.

We can find that $\nabla \cdot H = -\nabla \cdot M$ so the divergence of the magnetic field is negative divergence of M . This is very easy to show here because this term divergence of the magnetic induction will be 0 so the divergence of the magnetic field will be negative divergence of the magnetization right.

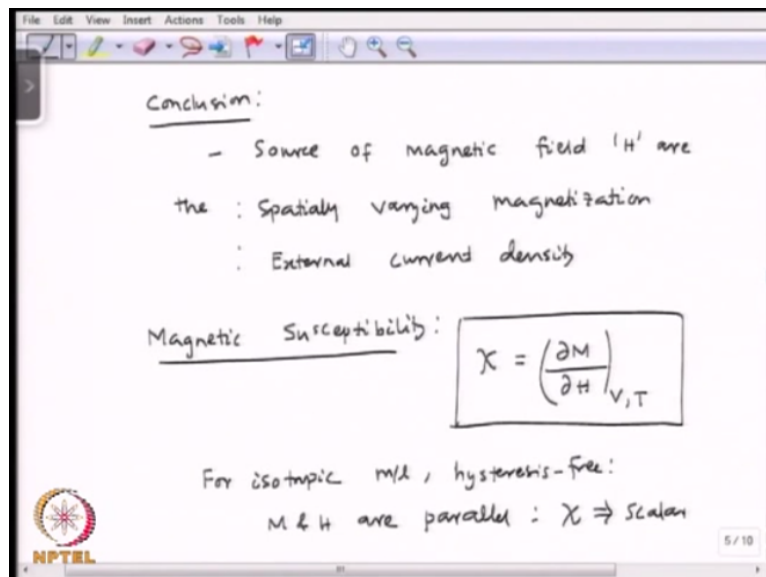

(Refer Slide Time: 23:42)

$\rightarrow \nabla \cdot H = -\nabla \cdot M \quad \text{--- (1)}$
 Use $J_{\text{mag}} = \nabla \times M$ and $H = \frac{1}{\mu_0} B - M$
 $\nabla \times B = \mu_0 J_{\text{ext}} + \mu_0 J_{\text{mag}}$
 $\nabla \times H = J_{\text{ext}} \quad \text{--- (2)}$
 Conclusion:

Now if we use the magnetic current density, which is $\nabla \times \mathbf{M}$ and you also use the magnetic field as $1/\mu_0 \mathbf{B}$, which is magnetic induction-magnetization and you know if you substitute that in the equation $\nabla \times \mathbf{B} = \mu_0 \mathbf{J}_{\text{external}} + \mu_0 \mathbf{J}_{\text{magnetic}}$ okay so use these 2 conditions in this equation you can show that $\nabla \times \mathbf{H} = \mathbf{J}_{\text{external}}$ okay. So what do we see here so this we have you know these 2 equations.

We can say that the conclusion okay is that the source of magnetic field is the spatial variation of the magnetization and the magnetic current density okay.

(Refer Slide Time: 25:10)

Conclusion:

- Source of magnetic field \mathbf{H} are the : Spatially varying magnetization : External current density

Magnetic Susceptibility:

$$\chi = \left(\frac{\partial M}{\partial H} \right)_{V,T}$$

For isotropic m/h , hysteresis-free:
 \mathbf{M} & \mathbf{H} are parallel : $\chi \Rightarrow \text{Scalar}$

So if we compare these 2 we can say that the source of the magnetic field \mathbf{H} are the spatially varying magnetization okay, which is shown in equation 1 okay, this is the spatially varying magnetization and also we have the external current density as you see here in this equation okay. Now with that we can define it on called magnetic susceptibility and this can be defined as the change in the magnetization over the change in the magnetic field at constant volume and temperature okay.

So for isotropic material and with hysteresis-free have no hysteresis then you know the magnetization and the magnetic field \mathbf{M} and \mathbf{H} are parallel okay so in that case the susceptibility is a scalar okay right.

(Refer Slide Time: 27:34)

For isotropic mtl, hysteresis-free:
 M & H are parallel: $\chi \Rightarrow \text{scalar}$

Analogy with $D = \epsilon E$

$$M = \chi H$$

$$B = \mu_0 (H + M) = \mu_0 (1 + \chi) H$$

$$= \mu_0 \mu_r H = \mu H$$

NPTEL 5/10

Now if we do an analogy with the electrical displacement as $\epsilon \cdot \text{electric field}$ okay so we can write magnetization as $\text{susceptibility} \cdot \text{the magnetic field}$ okay and we can also write that B the magnetic induction is $\mu_0 \cdot H + M$ magnetic field + magnetization, which is $\mu_0 \cdot 1 + \text{susceptibility}$ into the magnetic field, which will be $= \mu_0 \mu_r \cdot \text{magnetic field}$, which is $\mu \cdot H$ okay.

(Refer Slide Time: 28:42)

$$M = \chi H$$

$$B = \mu_0 (H + M) = \mu_0 (1 + \chi) H$$

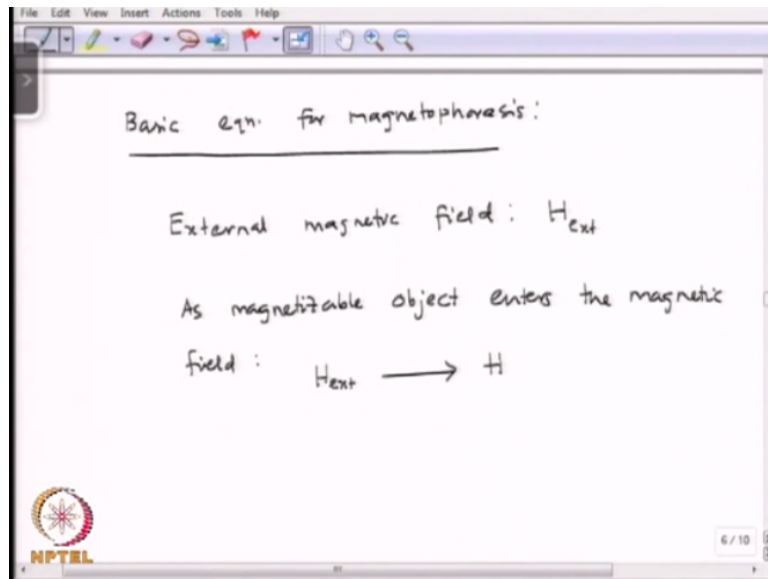

$$= \mu_0 \mu_r H = \mu H$$

\uparrow relative permeability. \uparrow permeability

NPTEL 5/10

So you have these 2 important equations and here μ is the permeability and μ_r is the relative permeability okay. So with that let us move on and try to derive an expression for magnetic force that is acting on a magnetizable particle in an inhomogeneous magnetic field okay.

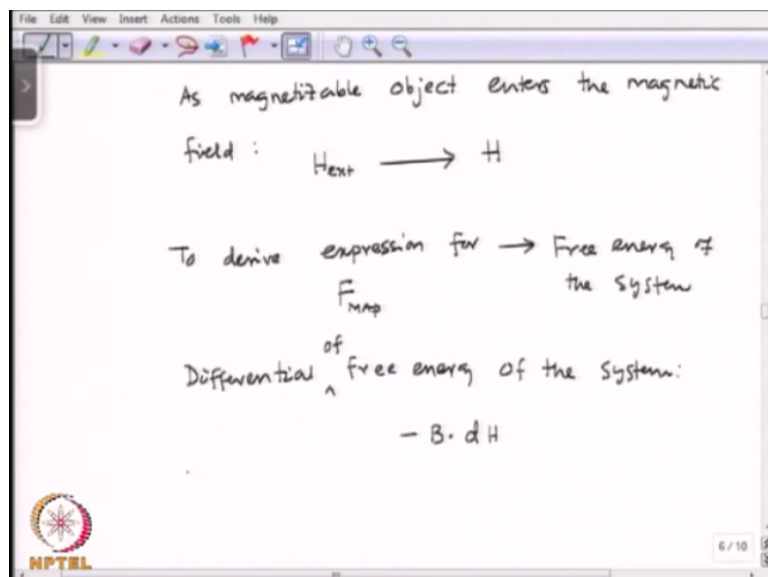

(Refer Slide Time: 29:22)

So let us look at the basic equation for magnetophoresis and here we say that the external magnetic field which is on perturbed before we have the magnetizable object in the magnetic field is H external okay so we have a magnetic field which is H external and this is the unperturbed magnetic field before any magnetizable object enters the magnetic field. Now when the object enters the magnetic field.

As the magnetizable object enter the magnetic field the H external the external magnetic field changes to some H okay.

(Refer Slide Time: 30:50)

Now we are trying to derive the magnetic force now to derive expression for magnetic force okay F magnetophoresis, we need to consider the free energy of the system okay. So you know we have to consider the free energy of the system and the differential of free energy of

the object the magnetizable object is given by $-B \cdot dH$ okay. So that is the free energy of the system okay is $-B \cdot dH$.

Now when the magnetizable object goes through some displacement in the magnetic field, we going to know what is the change in the free energy that is happening okay.

(Refer Slide Time: 32:25)

To derive expression for the free energy of the system

Differential of free energy of the system:

$$-B \cdot dH$$

Change in the free energy of object due to Spatial displacement (δr):

$$\boxed{dE = -F \cdot \delta r}$$

NPTEL

So you know the change in the free energy of object due to spatial displacement δr so dE the change in the free energy is going to be $-F \cdot \delta r$ okay and if you analyze this equation okay.

(Refer Slide Time: 33:08)

Spatial displacement (δr):

$$\boxed{dE = -F \cdot \delta r}$$

Analysis $\rightarrow F_{\text{mag}}$

$$F = \mu_0 \int_{\text{body}} dr (M \cdot \nabla) H_{\text{ext}} \rightarrow \nabla \times H_{\text{ext}} = 0$$

Static field

NPTEL

And if you analyze this equation we get an expression for the magnetophoretic force okay. So F is given by $\mu_0 \cdot \text{integration over the volume } dr \cdot M \cdot \text{gradient of the external magnetic field}$.

So this is the expression for the force provided $\nabla \times \mathbf{H}_{\text{ext}} = 0$ so the external electric field is irrotational. We are talking about a static field okay.

(Refer Slide Time: 34:07)

Analysis $\rightarrow F_{\text{Mag}}$

$$F = \mu_0 \int_{\text{body}} d\mathbf{r} (\mathbf{M} \cdot \nabla) \mathbf{H}_{\text{ext}}$$

$\nabla \times \mathbf{H}_{\text{ext}} = 0$ (Static field)

$$\nabla \times \mathbf{E} = 0 \rightarrow \mathbf{E} = -\nabla \phi$$

Now you know this is similar to what we have seen in the electric field so for the electric field we have seen $\nabla \times \mathbf{E} = 0$ and from that we can derive that electric field is $-\nabla \phi$ okay. So similar to in electric field we have defined electric field is negative of gradient of the potential, here we can define something called magnetic potential okay.

(Refer Slide Time: 34:38)

body

Static field

$$\nabla \times \mathbf{E} = 0 \rightarrow \mathbf{E} = -\nabla \phi$$

Magnetic potential: $\mathbf{H}_{\text{ext}} = -\nabla \phi_m$

Magnetizable sphere, the expression for magnetization 'M':

$$\mathbf{M} = 3 \left(\frac{\mu - \mu_0}{\mu + 2\mu_0} \right) \mathbf{H}_{\text{ext}}$$

So we define something called the magnetic potential so we can say \mathbf{H}_{ext} is negative of gradient of ϕ_m okay and for a magnetizable sphere we have a magnetizable sphere, the expression for magnetization \mathbf{M} so the expression for the magnetization would look similar to

the polarization in case of the electrostatic okay. So that the expression for the magnetization M is $3\mu_0/\mu+2\mu_0 \cdot H$ external okay.

(Refer Slide Time: 36:00)

Handwritten notes on a whiteboard:

Magnetizable sphere, the expression for magnetization 'M':

$$M = 3 \left(\frac{\mu - \mu_0}{\mu + 2\mu_0} \right) H_{\text{ext}}$$

$$p = 4\pi\epsilon_1 \left(\frac{\epsilon_2 - \epsilon_1}{\epsilon_2 + 2\epsilon_1} \right) a^3 E_0$$

$$F_{\text{MAP}}(r_0) = 2\pi\mu_0 K(\mu_0, \mu) a^3 \nabla [H_{\text{ext}}^2(r_0)]$$

NPTEL logo and slide number 6/10 are visible at the bottom.

And this is similar to the polarization p which we saw $4\pi\epsilon_1 \epsilon_2 \epsilon_1 / (\epsilon_2 + 2\epsilon_1) a^3 E_0$ okay so this is what we saw in electrostatic. Here in magnetostatic this is the expression for the magnetization. So we can write down the expression for the magnetic force F_{MAP} will be $2\pi\mu_0$ this is equivalent to the Clausius-Mossotti factor $\mu_0 \mu a^3 \nabla$ of the square of the external magnetic field okay.

So this is at r_0 . So here we see that the expression for the magnetophoretic force is very similar to the expression for the dielectrophoretic force. In case of the dielectrophoretic force, we had the dielectrophoretic force was varying as the square of the gradient of the electric field, here the magnetophoretic force is square of the gradient of the magnetic field and similar to the dielectrophoretic force, the magnetophoretic force varies as the cube of the size of the object okay.

(Refer Slide Time: 37:36)

$$\rightarrow F_{map} \sim \nabla [H_{ext}^2(y_0)]$$

$$\rightarrow F_{map} \sim a^3$$

$$\sim K(\mu_0, \mu)$$

So that is what we observe here okay. So what we see is FMAP varies as the gradient of the square of the external magnetic field and the magnetophoretic force varies as a cube and is also dependent on something similar to the Clausius-Mossotti factor okay, but it is in terms of the magnetic you know permeabilities okay so with that let us move on and talk about the electrocapillary effect okay.

So first of all what we mean by electrocapillary effect? Electrocapillary effect is the electrostatic effect at the interface between different phases okay.

(Refer Slide Time: 38:35)

Electrocapillary Effect:

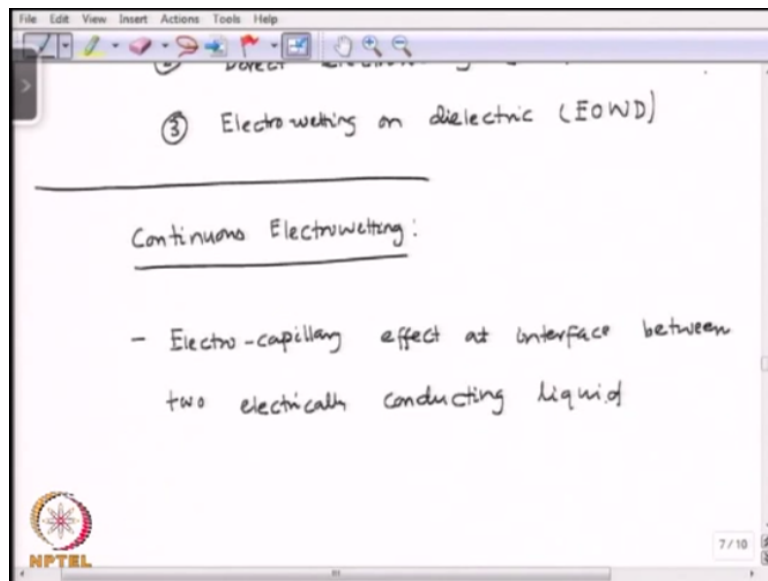

Electrostatic effect at interfaces of different phase

- ① Continuous electrowetting (CEOW)
- ② Direct electrowetting (DEW)
- ③ Electrowetting on dielectric (EOWD)

So we look at electrocapillary effect. Electrocapillary effect is the electrostatic effect at interfaces of different phases okay so here we will be talking about the continuous

electrowetting CEOW, will be talking about direct electrowetting DEW and we will also talk about the electrowetting on dielectric EO okay right.

(Refer Slide Time: 40:18)

So first let us talk about what we mean by continuous electrowetting. Continuous electrowetting means it is the electrocapillary effect that exists at the interfaces between 2 different you know fluids or liquids okay electrically conductive liquids that have non-zero electrical conductivity.

So in that case we would have an electrical double layer that would exist at the interface and so you know because of the charged situation if we apply an electric field one of the phase would start to move relative to the other okay. So this is what we will be seeing here. So by continuous electrowetting we mean that it is the electrocapillary effect at interface between 2 electrically conducting liquid okay.

(Refer Slide Time: 41:46)

So you can see this here. We are talking about the interface between 2 electrical conductive liquids so you have 1 liquid here which is in the form of droplet and this is the other liquid that we are talking about which is the continuous phase and because of non-zero conductivity at the interface, we would have an electrical double layer that would exist and if we apply an electric field okay.

So this droplet here would act as a charged particle okay and we apply an electric field this droplet would tend to move relative to the liquid, which is phase 2 so phase 1 would tend to move relative to phase 2 okay. Now if you do a force balance you know so the force the electrical force would try to carry this droplet and it will be opposed by the drag force okay so if you look at a force balance on this droplet will have electrical force will be=to the drag force.

(Refer Slide Time: 43:22)

Force balance: electrical = Drag force
on droplet force

$$\left(\frac{F_{el}}{Vol.}\right) \rightarrow q_s E_{el} = \frac{6\eta u}{H}$$

avg. vel.
size of droplet.

Hagen-Poiseuille model: $\frac{F_d}{V} = \frac{6\pi\eta a u}{\pi a H} = \left(\frac{6\eta u}{H}\right)$

q_s = surface charge of droplet
 E_{el} = electric field
 η = viscosity.

NPTEL

So we can write the expression for the electrical field force is q_s is the surface charge on the droplet which is into the electric field okay so that is the electrical force per unit volume okay. So this is the F electrical force per unit volume and so we have to equate drag force per unit volume and we know the expression for the drag force. You know we can assume that Hagen–Poiseuille model can say it is Hagen–Poiseuille model.

So if you do that we can we know that the drag force is $6\pi\eta a u$ so we are talking about per unit volume so here if you look at the droplet, it is looking like an cylinder. Let say a is the radius of the cylinder so we have $\pi a^2 H$ okay so it will be $\pi a^2 H$ so that will be you know $6\eta u/H$ so this will be $6\eta u/H$ right. So what are the terms here?

Q_s is the surface charge of droplet and E is the electric field, η is the viscosity and H is the size of the droplet and u is the average velocity okay. So from here we can predict how quickly the droplet is going to move.

(Refer Slide Time: 45:53)

q_s = surface charge of droplet
 E = electric field
 η = viscosity,

Droplet velocity : $u = \left(\frac{q_s H}{6 \eta L} \right) \Delta \phi$ $E = \frac{\Delta \phi}{L}$

NPTEL

So the droplet velocity u is going to be from this equation we can find what is the value of u okay. So u is going to be $q_s \cdot H / 6 \eta L \cdot \Delta \phi$ okay. So that is the expression for the droplet velocity so the electric field is represented by $\Delta \phi / L$ okay where L is the length scale of the droplet in this case okay. So let us move on and talk about direct electrowetting.

(Refer Slide Time: 47:00)

η = viscosity,

Droplet velocity : $u = \left(\frac{q_s H}{6 \eta L} \right) \Delta \phi$ $E = \frac{\Delta \phi}{L}$

Direct Electro-wetting:
 - Electro-capillary effect at the interface between electrically conducting liquid and solid electrode

NPTEL

Direct electrowetting is the electrocapillary effect or the interface between a liquid phase and a solid electrode okay. So direct electrowetting is the electrocapillary effect at the interface between electrically conducting liquid and solid electrode okay.

(Refer Slide Time: 48:08)

So as you see here we have a solid electrode okay, this is the electrode and we have an electrolyte okay. So in this case we can expect direct electrowetting at the interface between the electrically conducting liquid and the solid electrode. We would have an electrical double layer that would exist okay because the liquid has non-zero conductivity. So we would have an electrical this is the electrical double layer okay.

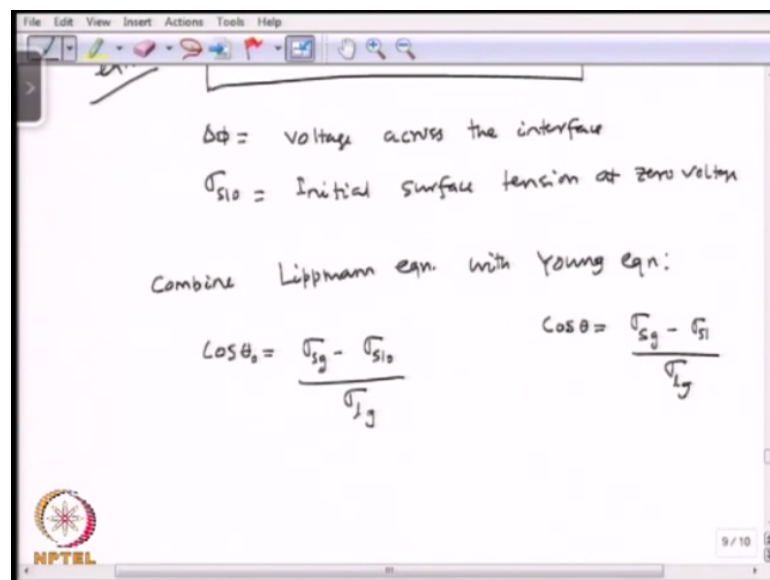

So we can write the expression for the capacitance across the electrical double layer. We can write down the capacitance across electrical double layer so you can write C_{EDL} will be $= \epsilon_0 \epsilon_r / \lambda_D$ okay. So what do we see here is that the surface energy is going to reduce because there are some charges which are going to be stored in the form of capacitance inside the electrical double layer okay.

(Refer Slide Time: 49:30)

So what would happen is the surface energy reduced by the amount stored in capacitor and so in that case you can write the relation between surface tension and applied voltage and this is given by the Lippmann equation okay so you know this can be given by the Lippmann equation. So the Lippmann equation can be written in this form σ_{sl} is going to be $\sigma_{sl0} - \frac{1}{2} \epsilon_0 \epsilon_r \Delta \phi^2$ okay.

(Refer Slide Time: 50:55)

Handwritten notes on a digital whiteboard:

- $\Delta \phi$ = voltage across the interface
- σ_{sl0} = Initial surface tension at zero voltage
- Combine Lippmann eqn. with Young eqn:
- $\cos \theta_0 = \frac{\sigma_{sg} - \sigma_{sl0}}{\sigma_{lg}}$
- $\cos \theta = \frac{\sigma_{sg} - \sigma_{sl}}{\sigma_{lg}}$

The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar with various drawing tools. An NPTEL logo is visible in the bottom left corner, and a slide number '9/10' is in the bottom right.

And here $\Delta \phi$ is the voltage across the interface and σ_{sl0} is the initial surface tension at 0 voltage okay. Now if we combine this Lippmann equation okay with the Young equation that we studied in capillary flows. So combine Lippmann equation with Young equation. So Young equation said that $\cos \theta$ is going to be $\frac{\sigma_{sg} - \sigma_{sl}}{\sigma_{lg}}$.

So $\cos \theta_0$ will be $\frac{\sigma_{sg} - \sigma_{sl0}}{\sigma_{lg}}$ okay.

(Refer Slide Time: 52:21)

Handwritten derivation on a whiteboard:

$$\cos \theta - \cos \theta_0 = - \left(\frac{\sigma_{sl} - \sigma_{sl0}}{\sigma_{lg}} \right) = \frac{C_{EDL} \Delta \phi^2}{2}$$

$$\Rightarrow \theta = \cos^{-1} \left[\cos \theta_0 + \frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}} \right]$$

An arrow points to the term $\frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}}$ with the label "-ve".

NPTEL logo and slide number 9/10 are visible at the bottom.

So we can do some math $\cos \theta - \cos \theta_0$ will be $= -\sigma_{sl} - \sigma_{sl0} / \sigma_{lg}$ liquid gas, which is nothing but equal to in the form of capacitance and electrical potential you can write this, this is going to be $C_{EDL} \Delta \phi^2 / 2$ okay. So from here we can predict θ is going to be \cos^{-1} of $\cos \theta_0 + C_{EDL} \Delta \phi^2 / 2 \sigma_{lg}$ okay. So what do we see here?

We see that a surface, which is originally hydrophobic can be made hydrophilic okay. So you know if the surface is hydrophobic initially, this will be negative right and you can store some energy you can take some energy out of the surface energy and dissipate and store that in the form of the capacitor charged inside the electrical double layer okay. If you do that, the contact angle is going to be reduced okay so $\cos \theta$ is going to be positive okay.

(Refer Slide Time: 54:04)

Handwritten notes on a whiteboard:

$$\Rightarrow \theta = \cos^{-1} \left[\cos \theta_0 + \frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}} \right]$$

An arrow points to the term $\frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}}$ with the label "-ve".

→ original hydrophobic surface ($\theta_0 > 90^\circ$)

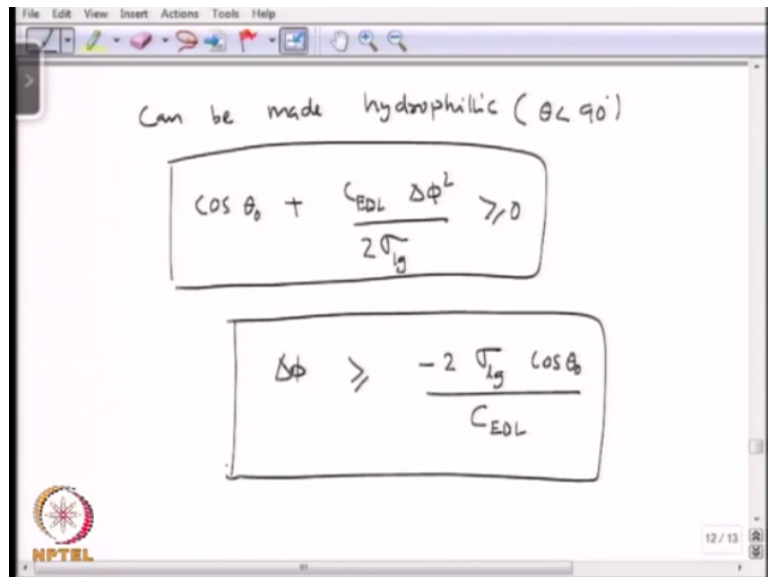

Can be made hydrophilic ($\theta < 90^\circ$)

$$\cos \theta_0 + \frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}} > 0$$

NPTEL logo and slide number 12/13 are visible at the bottom.

So what we see here that original hydrophobic surface can be made hydrophilic okay. So hydrophilic means θ_0 will be < 90 and initially θ_0 will be > 90 and θ_0 let us not call it θ_0 this is θ is < 90 . So what will be the critical potential at which an original hydrophobic surface will become hydrophilic? So in that case $\cos \theta_0 + \frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}} \geq 0$.

(Refer Slide Time: 55:12)

Can be made hydrophilic ($\theta < 90^\circ$)

$$\cos \theta_0 + \frac{C_{EDL} \Delta \phi^2}{2 \sigma_{lg}} \geq 0$$

$$\Delta \phi \geq \frac{-2 \sigma_{lg} \cos \theta_0}{C_{EDL}}$$

Or if you simplify we can find out that the electrical potential will be $\geq -2 \sigma_{lg} \cos \theta_0 / C_{EDL}$ okay. So we found the expression for the minimum potential that is required to make an original hydrophobic surface to hydrophilic. Now the problem with the direct electrowetting is that the capacitance for a given set of liquid and electrode surface is fixed. So what we can do is we can add another insulating layer on the electrode okay.

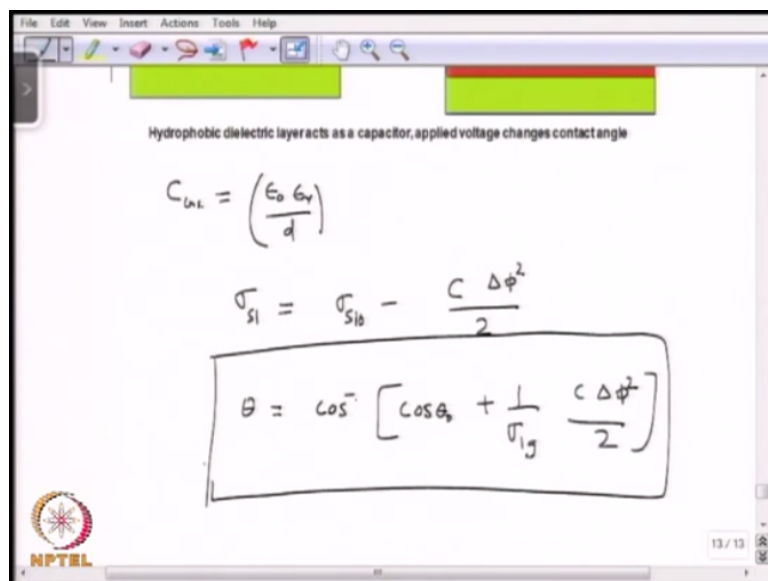

So that the equivalent capacitance of the electrical double layer plus an insulating layer can be controlled by changing the thickness of the insulating layer okay and that is known as the direct electrowetting on dielectrics.

(Refer Slide Time: 56:16)

So we talk about direct electrowetting on dielectrics. So as you see here instead of having the electric layer we add one more insulating layer here, so we have the capacitance of this insulating layer plus the capacitance of the electrical double layer. So the capacitance of the insulating layer, which can be controlled is given by epsilon 0 epsilon r/d okay.

(Refer Slide Time: 57:08)

And so in that case we would have sigma Sl as sigma Sl0-C del phi square/2 so you can write theta as cos inverse cos theta 0+1/sigma lg*C del phi square/2 okay. So here in addition to you know making the surface to make an originally hydrophobic surface hydrophilic you would have a control and that control can be achieved by controlling the thickness of the insulating layer okay.

(Refer Slide Time: 58:01)

The image shows a digital whiteboard interface with a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar. At the top, there are labels S_1 , S_{10} , and $\frac{2}{2}$. The main content is a boxed equation:

$$\theta = \cos^{-1} \left[\cos \theta_0 + \frac{1}{\sigma_{ig}} \frac{c \Delta \phi^2}{2} \right]$$

Below the equation, an arrow points to the following text:

→ Capacitance can be controlled by controlling the coating thickness of the insulating layer (Teflon)

At the bottom left is the NPTEL logo, and at the bottom right is a page indicator showing 13 / 13.

So here the capacitance can be controlled by controlling the coating thickness of the insulating layer which could be for example Teflon okay. So with that let us stop here.
