Week – 01
Lecture – 03
Tutorial 1

We will do two problems with the topics which we have discussed in the last class. So, this is going to be very short tutorial.

(Refer Slide Time: 00:27)

We will try to see what property changes that happen, what are the kinds of property changes that happens in a fluid that undergoes some process with the very specific process that we have discussed in the last class. So, the first question is say, a fluid let us take air is compressed and you know the T_1 and P_1 and you also know the T_2 and P_2 .

So, it takes two paths - one is, first an isentropic process to reach an intermediate state T_1' and P_1' then constant pressure process to reach T_2 and P_2 . B, an irreversible process to reach T_2 and P_2 , how do we go about doing this? So, an isentropic process to reach say T_1 and then a constant process to reach P_2 , so obviously, this process should have reached P_2 here and with constant pressure it will reach P_2 ,

fine. So, there is two rise of reaching the state two. So, let us drop this process in (Refer Time: 03:20) diagram first. So, any problem like this should be attempted with PV diagram or a T-s diagram, drawn and process clearly understood.

T, S, so let us take the process A. So, from point 1 it goes to an intermediate state and isentropic process which means the entropy is constant, entropy does not change. So, this is your 1 dash and then you have a constant pressure process to reach 2. So, the question is - find the entropy change essentially it comprise S 2 minus S 1? Find S 2 minus S 1 or delta S of the process. So, this is my delta S. So, this is process a, process b is an irreversible process which goes here that is your b. How do we do this? It is a constant isentropic process; so we know the relations, what are the relations? T_1 by T_1 dash equals P_1 by P_1 dash to the power γ minus 1 by γ . So, you will get T_1 .

So, for a given P_1 and T_1 dash this is also a P_2 because after that it is an isentropic process, so P_1 dash is same as P_2 for a given gas here we have taken air so the γ is 1.4. So, you could find T_1 dash. So, once you know T_1 dash. So, these two quantities have given.

(Refer Slide Time: 06:23)

$T_1 = 289 \text{ K}$
 $T_2 = 567 \text{ K}$
 $P_1 = 1.38 \times 10^5 \text{ N/m}^2$
 $P_2 = 4.14 \times 10^5 \text{ N/m}^2$
 $C_p = 1004 \text{ J/kgK}$
 $\gamma = 1.4$
 $T_1' = 396 \text{ K}$
 $T ds = dh - v dp$
 process 1-2, $dp = 0$

$\Delta S = C_p \ln \left(\frac{T_2}{T_1} \right)$
 $= 1004 \ln \left(\frac{567}{289} \right)$
 $= 1004 \ln (1.96)$
 $= 1004 \times 0.67$
 $= 672 \text{ J/kgK}$
 process ① $\rightarrow 1-1-2$
 process ②
 $\Delta S = C_p \ln \left(\frac{T_2}{T_1} \right) - R \ln \left(\frac{P_2}{P_1} \right)$
 $\Delta S = 1004 \ln (1.96) - 287 \ln (3)$
 $\Delta S = 672 - 287 \times 1.1$
 $\Delta S = 672 - 316$
 $\Delta S = 356 \text{ J/kgK}$

So T_1 , P_1 , T_2 , P_2 is given quantities. So, let us take some numerical value, what I have here is T_1 is 289 Kelvin, T_2 is 567 Kelvin, P_1 is 1.38×10^5 Newton per meter square, P_2 is 4.14×10^5 Newton per meter square and your C_p is 1.004 Joule per kg Kelvin and you can take γ to be 1.4.

For these numerical values you could actually find T_1 . So, T_1 is going to be T_1 dash is approximately for these values, T_1 dash is approximately 396 Kelvin and you could use the equation $T ds = dh - v dp$. So, the process 1 prime to 2 you are dp is 0. So, your ds is $C_p dT/T$ or your ΔS is $C_p \ln$ given by T_2 or T_1 prime by T_2 prime. You could get the value to be (Refer Time: 08:52) this T_2 by T_1 prime. So, if this is 1.004 or $\ln T_2$ is, T_2 is what? 567 by T_2 prime is 396 Kelvin. So, it is going to be approximately something, you could evaluate that. So, it is going to be joule per kg Kelvin.

This is for your process a which is from point 1 to state 1 prime to state 2 for irreversible process you could use the equation that we had learnt $C_p \ln T_2$ by T_1 minus $R \ln T_2$ by T_1 . T_2 is known, P_2 is known, is this. Find your ΔS , so if these has these two process gives you essentially the same value because entropy is a point function, entropy is a property you are going to get the difference between these two processes, the entropy change that is occurring in these two process are going to be the same.

(Refer Slide Time: 11:00)

Question 2 - I have at that. So, the fluid goes from state 1 to state 2, your P 1 has 260 degree Celsius, v 1 has 75 meters per second, P 1 has 140 kilo Pascal, P 2 is 30 kilo Pascal and T 2 is 207 degree Celsius.

Let us forget about the velocity for the time being. Find say delta S? So, it is essentially evaluation of this equation; find delta S if the fluid is air then the example I have here is Argon, 3 - steam. So, it is a very symbol substitution. So, you have two quantities P 1, T 1 - the pressure and temperature are two states. So, some process that is happening between state 1 and 2, you have that pressure and temperature here. Use the relation that we had just now written $C_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$.

The only difference here is the fluids. So, only difference here is the value of C p and R. Now the universal gas constant from universal gas constant finds the universal gas constant 8.314 kilo Joule per Kelvin. And the molecular mass of air, molecular mass of argon, molecular mass of steam, if you know this you can find R and substitute R here.

(Refer Slide Time: 14:06)

If you know R , then C_p value is of air, C_p values of argon, C_p value of steam, you should get the entropy change essentially. So, it is a symbol substitution. The tutorial for this week would be based on.
