Today we will discuss the differential form of energy equation and we will derive the pressure energy relation.

(Refer Slide Time: 00:29)

So, we will, I will start from where we had left in the last class. So, we have seen this equation, where  $Q$  is the total heat supplied,  $W_s$  is the shaft work,  $e$  is the internal energy and  $V$  is the volume which we have reduced to this form, out minus in, for one exit and one entry. So, that is a reduced form, 1D, 1D equation of that, we will apply this to infinitesimally small control volume and derive the differential form.

$Q$  here,  $Q$  is  $1$  by  $m$  dot  $dQ$  by  $dt$  and  $W_s$  is  $1$  by  $m$  dot  $dW_s$  by  $dt$ . So, equation 1 apply to infinitesimally small control volume and that is how we derive the differential form of any governing equation, any kind of equation.

(Refer Slide Time: 02:46)

So, I have a control volume which is infinitesimally small, the dimensions is given, the characteristic dimension is  $dx$ . I have an inlet, outlet. This derivation is also true for 3rd dimensions as long as we take the 3rd dimension equation. So, let us stick to 1D equation. So, at the inlet the density is given by  $\rho$ , pressure  $P$ , velocity, velocity  $v$  and what are the quantity, internal energy  $u$  and the total energy small  $e$ . At the exit, it is  $\rho + d\rho$ ,  $P + dP$ ,  $v + dv$  and  $e + de$ .

So, we write this equation,  $Q - W_s + e_{out} - e_{in} = 0$ . We substitute the out quantities, out are these quantities, so instead of,  $e + de$ ,  $e + de + P + dP$  multiplied by  $v + dv$ , which is the out quantity, minus the in quantity, which is  $e + Pv$ .

Student: (Refer Time: 05:50).

Pardon.

Student: (Refer Time: 05:54).

$W_s$ , I expand this,  $e$  and  $e$  cancels out, I, we will expanded as  $u + du + v + dv$  the whole square by 2 plus  $gz + dz$  plus this quantity, which is pressure and volume  $P + dP$  multiplied by  $v + dv$  minus  $u + v^2/2 + gz + Pv$ . So,  $Q$  equals  $W_s$ . So, this  $u$  and this  $u$  cancel out, what is left is  $du$ . So, this  $v^2$  and  $v^2$

cancels out. So, you have  $2v dv$  by 2 plus  $dv$  the whole square by 4 plus  $gdz$ . So,  $Pv$   $Pv$  cancels out, you have  $v dP$  plus  $P dv$  and (Refer Time: 08:37).

So, I have expanded this and this and cancelled out all these terms.

Student: (Refer Time: 08:48).

2, there is, this is, this is correct.  $dv$  square by 2, yes, this is  $dv$  square by 2, neglect your higher order terms. So, this goes, this goes, so you are, have left with  $Q$  equals  $W$  s plus  $du$  plus  $dv$  square by 2 plus  $gdz$  plus this is  $d$  of  $Pv$ . So, that is nothing but  $W$  s plus  $dh$  plus  $dv$  square by 2 plus  $gdz$ .

So, this is something that is applied to this infinitesimally small volume and even if it is 3rd dimension you just consider this differential as the third dimension. Here, the  $Q$  and  $ds$  is also the small differential because what is going in as  $Q$  is  $dW$  for a small differential volume and work that is obtained is  $W$  s. So, ideally this should be  $dQ$  and  $ds$ . So, this would be  $dQ$  and  $ds$  that would complete the differential form.

So, this is the energy equation in the differential form.

(Refer Slide Time: 12:00)

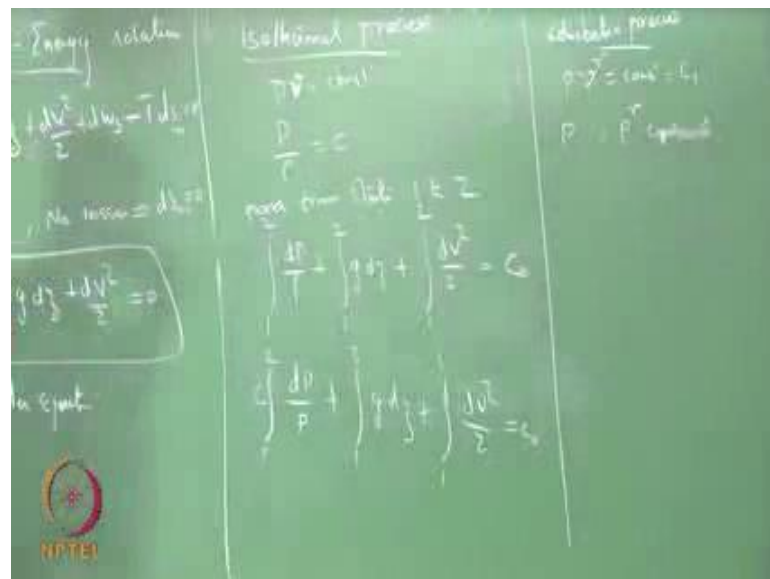

Now, we will proceed further.  $vdP$ , so this is, one of these are called Gibbs equation. So,  $dh$  we substitute from this equation. So,  $dh$  from equation 2, which is  $dq$  minus  $W$  s minus  $dv$  square by 2 minus  $gz$  from equation 2, which is your energy equation.

Now,  $Tds$  contains two components, two components are  $Tds$  irreversible plus  $Tds$  reversible and from the 2nd law we have  $Tds$  reversible equals  $q$ , the heat input, okay. So, substitute these equations, say 3 and 4 in the 1st equation, such say, this is your 1st equation. So, this is  $Tds$  reversible plus  $Tds$  irreversible equals  $dq$  minus  $dW_s$  minus  $dv$  square by 2 minus  $gdz$  minus  $vdP$ , which I replace it as  $dP$  by  $\rho$ . So, now,  $dq$  is this  $T$  irreversible. So, I cancel out this term. So, my, sorry, so I cancel out  $dq$  with the irreversible entropy change. So, what is left here is  $dP$  by  $\rho$  plus  $gdz$  plus  $dv$  square by 2 plus  $dW_s$  plus  $Tds$  irreversible equals 0.

Even though  $q$  is explicitly absent, this is also valid for process with  $q$  because we did not assume  $q$  to be absent here, we just cancelled out  $q$  with the reversible entropy change, okay. So, if we have a system with  $q$  input, this equation is still valid and this equation is, I rewrite this here, 0.

So, if shaft work is 0,  $dW_s$  is 0 and if no losses implying  $d$  irreversible is 0, so entropy change due to irreversible process is 0. I lose these two terms, in the end what is left is  $dP$  by  $\rho$  plus  $gdz$  plus  $dv$  square by 2 equals 0, which is your Euler equation, 1D Euler equation. So, the differential form of energy equation from the differential form of energy equation, we get these equations.

(Refer Slide Time: 18:19)

So, if the process is isothermal. So, if the process is, I have  $Pv$  equals constant,  $P$  volume is constant or  $P$  by  $\rho$  equals constant. So, for process 1 to 2, process from state 1 to 2,

you integrate this equation to get, so from process 1 to 2  $dP$  by  $\rho$  plus integral  $g dz$  1 to 2 plus integral  $dv^2$  by 2, 1 to 2 equals some constant where you substitute, instead of  $\rho$  I substitute  $dP$  by  $P$  into some constant  $c$  plus this.

So, instead if the process is adiabatic,  $Pv^\gamma$  equals constant. You substitute the appropriate value of  $P$ ; substitute the value of  $\rho$  in terms of  $P$  with this equation and get a different form of equation, okay. So, these are the energy equations for isothermal and adiabatic process.

For an incompressible flow the density is constant. So, it is convenient to take it out and you can integrate and get the Bernoulli's equation. So, this, this constant is different constant from this constant. So, this is  $c_0$  this again is a different constant. So, this would be  $c_1$  and you integrate this equation with the appropriate value of  $P$ .

So, what we are done today is the differential form of the energy equation and from which we have derived the pressure energy relation and we had seen some special cases. We will be using this equation further in our gas dynamic course. So, that is for the day.
