Lecture – 30
Kinetics: Angular Motion Part II

(Refer Slide Time: 00:41)

Angular motion Arm is assumed to be weightless, and of length l
 $m \rightarrow$ mass of dumbbell

Diagram shows a person's arm holding a dumbbell. The arm is assumed to be weightless and of length l . The dumbbell has mass m . The arm is at an angle θ to the vertical. The dumbbell is at point P. The forces acting on the dumbbell are the reaction forces J_x and J_y at the shoulder, the weight mg acting downwards, and the deltoid muscle force F_{Δ} acting at an angle ϕ to the arm.

Handwritten equations:

$$\vec{r}_{p/o} = l \hat{e}_r$$

$$\vec{v}_p = \frac{d\vec{r}_{p/o}}{dt} = l \frac{d\hat{e}_r}{dt} = l \dot{\theta} \hat{e}_\theta$$

$$\vec{a}_p = \frac{d\vec{v}_p}{dt} = l \ddot{\theta} \hat{e}_\theta + l \dot{\theta} \frac{d\hat{e}_\theta}{dt} = l \ddot{\theta} \hat{e}_\theta - l \dot{\theta}^2 \hat{e}_r$$

$\dot{\theta} \rightarrow \omega$ angular vel.
 $\ddot{\theta} \rightarrow \alpha$ angular acceleration

$$\Sigma F_r = m a_r$$

$$\Sigma F_\theta = m a_\theta$$

$$\Sigma M_o = \frac{dH_o}{dt}$$

$$H_o = \vec{r} \times m \vec{v}_p = l \hat{e}_r \times m l \dot{\theta} \hat{e}_\theta = m l^2 \dot{\theta} \hat{k}$$

So, yesterday we looked at the angular momentum principle, and so that combined with the Newton's laws will give you the equations of motion for a rotating body. We will use that today to analyze this case of a person using their shoulder muscles to perform an exercise using dumbbells ok. So, let us say we have the arm is assumed to be weightless, and of length l , M is the mass of the dumbbell.

And we will assume that you know at the shoulder, you have reaction forces. So, if this is X , Y , this is J_x , and J_y , and there is also a resistive movement. So, this is not a free motion. So, it is not like a pin joint about which this arm is going to be freely moving. There is some resistance that is a resistance moment that is being provided by let us say an F_m ok, an abductor muscle abductor muscles of the shoulder. In this case, most likely the deltoid muscles, and let us say it acts as an angle ϕ to the long axis of the arm ok.

So, we will first in some cases of rotational motion, it is actually simpler to use a coordinate system, instead of the x , y Cartesian coordinate system. We will use a coordinate system that is the r θ system, so that is let us say I have a coordinate

system that is one aligned along the rod. So, let me call that unit vector \hat{e}_r , and I have \hat{e}_θ . So, one for rotational motion, it is convenient to have \hat{e}_r is your radial direction, and \hat{e}_θ is the unit vector. So, unit vector the caps denote the unit vector along radius direction, and \hat{e}_θ is the unit vector along the tangential direction.

And these can be related to so basically my coordinate system I have if this is \hat{i} , this is \hat{j} ok, then this is this is \hat{e}_r , this is \hat{e}_θ , and this angle is θ . So, I can relate the unit vectors of the two coordinate systems. I can say \hat{e}_r what would be \hat{e}_r , so if I take, I can project it on the \hat{i}, \hat{j} coordinate system, so I can say \hat{e}_r equals.

Student: (Refer Time: 05:05).

Yeah. So, this is $\sin \theta$, so I have $\sin \theta$ along the \hat{i} direction, it does not matter how, so here I am taking it.

Student: (Refer Time: 05:21).

In this, so depending on where how I take θ , I can write $\sin \theta \hat{i} - \cos \theta \hat{j}$ along \hat{j} ok, this is the y component. So, this is $\cos \theta$ it is a unit vector, so this is $\sin \theta$. So, \hat{e}_r is $\sin \theta$ along \hat{i} minus $\cos \theta$ along \hat{j} ; \hat{e}_θ is these vectors will change with θ \hat{e}_r and \hat{e}_θ will change. So, they are attached to the rotating body, and as the body rotates the coordinate system changes. So, \hat{e}_θ I can write it as if this angle is θ then.

Student: (Refer Time: 06:15).

This angle is also θ . The angle between \hat{e}_θ and \hat{i} , this angle will also be θ . So, I have $\cos \theta$ along \hat{i} plus $\sin \theta$ along \hat{j} . Now, these are changing vectors in direction right, unit vectors the magnitude remains the same, but the direction changes. So, I can find $\hat{e}_r \cdot \frac{d\hat{e}_r}{dt}$ is $\cos \theta$ into $\dot{\theta}$, because I do this by $d\theta$ times $\dot{\theta}$ along \hat{i} . Differential differentiating this term, I get plus $\sin \theta$ into $\dot{\theta}$ along \hat{j} .

Now, if you look at this, $\cos \theta \hat{i} + \sin \theta \hat{j}$ is nothing but \hat{e}_θ , so $\frac{d\hat{e}_r}{dt}$ the rate of change of this vector is nothing but $\dot{\theta}$ along \hat{e}_θ ok. Similarly, $\frac{d\hat{e}_\theta}{dt}$ by $\frac{d}{dt}$ equal to $\hat{e}_\theta \cdot \dot{\theta}$ if I differentiate that, I get minus $\sin \theta$ into $\dot{\theta}$ along \hat{i} plus $\cos \theta$ into $\dot{\theta}$ along \hat{j} this is nothing but.

Student: Minus.

Minus theta dot into \mathbf{e}_r ok so, we will use these, when we try to find the velocities. So, I can write the position of this mass ok. So, let us say this is P relative to O is nothing but l along \mathbf{e}_r ok. So, the velocity of this point P just d l will omit the O, because we are doing it with respect to it is understood that it is with respect to this inertial frame.

We are talking about the absolute velocity, so this is if I differentiate this l dot does not change, there is no change in l the mass is located in that, so l remains l and I get d \mathbf{e}_r by d t , which I know is theta dot \mathbf{e}_θ ok. So, l theta dot \mathbf{e}_θ . This is your omega \mathbf{r} that you are familiar with in rotational motion ok. Now, let us look at formulating.

Student: When will this is.

Yes.

Student: (Refer Time: 09:35).

That is an assumption we make. We assume that phi does not.

Student: Change.

Change, we assume the insertion angle of the muscle does not change in the course of the motion. So, now if I find the acceleration of P, I have to differentiate this again. So, I have l is constant first I differentiate theta dot, I get theta double dot along \mathbf{e}_θ , then \mathbf{e}_θ is also varying. So, I get l theta dot \mathbf{e}_θ dot ok. So, this is l theta double dot along \mathbf{e}_θ plus I know that \mathbf{e}_θ dot is minus theta dot \mathbf{e}_r , so this becomes minus l theta dot square \mathbf{e}_r . Again familiar from circular motion right so, this is theta double dot is generally designated as.

Student: Alpha

Alpha your angular acceleration, and theta dot is your omega ok. So, theta dot is omega angular velocity and theta double dot alpha angular acceleration ok. So, you can see that I can always express this now back in terms of sin theta and cos theta by going back to my i and j coordinates, because I know r , but I will just keep it like this for now ok.

So, now my equations of motion are so ΣF . So, let us say instead of J_x and J_y ok, it is more meaningful for me, because I am expressing in terms of e_r and e_θ . I will just call these reactions J_r and J_θ ok. I am taking two other orthogonal components for the joint reaction J_r and J_θ . So, now I can write ΣF_r my equations become ΣF_r equal to mass times the acceleration in the radial direction. ΣF_θ equals mass times the acceleration in the tangential direction. And then ΣM_o naught, because o is a point that is fixed I can write that as dH_o naught by dt , where H_o naught is the angular momentum about that point.

So, let us compute the angular momentum. I have only one particle here, I am assuming the rod is weightless ok. So, my H_o naught is only $r \times m v$ of $p_r \times p_\theta$ ok. I am using small m everywhere, so I will just change this. So, this is $r p_\theta$ is $l e_r \times m v_\theta$ is $l \dot{\theta} e_\theta$ ok. So, what does this give me? $M l^2 \dot{\theta}$ along $e_r \times e_\theta$ is again just $k m l^2 \dot{\theta}$ ok. You can also look at it as the moment of inertia of this mass about the point o mass times that l^2 here ok. So, now if I do dH_o naught by dt ok, I get dH_o naught by dt equals $m l^2 \ddot{\theta}$ and l^2 square do not change with time, so I get $\ddot{\theta}$. This is your familiar $I \alpha$ I_o naught α , this is α .

So, now I can write these three equations to solve for so I have to know θ , $\dot{\theta}$, $\ddot{\theta}$ or θ as a function of time ok. Knowing θ as a function of time, I can use these three equations to solve for the three unknowns, which are J_r , J_θ , and F_m ok. So, let me just write down those three equations. ΣF_r this gives me if I do that ΣF_r , first I can just solve for if I take moments about o , I am eliminating two of the unknowns. So, it is easier for me to write this equation first this equation.

So, I will do that I will do the ΣM_o naught that equation and I get $F_m \sin \phi$ times, I should know where the point of insertion is ok. So, let us say that is this distance let us say is a . Again known from anthropometric data ok so, I have $F_m \sin \phi$ into a minus $m g$ ok. The component perpendicular this is θ , so this is $m g \cos \theta$, and this component here is $m g \sin \theta$. So, and it is creating a clockwise moment. So, taking counterclockwise as positive, this becomes minus $m g \sin \theta$ into l that is equal to $m l^2 \ddot{\theta}$. I can write this as a scalar equation because everything is in the k direction, the planar case.

Then, so I can solve for F_m from this relation, then using the summation of forces in the r direction in the radial direction. I have J_r plus $m g \cos \theta$ minus $F_m \cos \phi$ is equal to $m a_r$, which is minus $m l \dot{\theta}^2$. And summing the forces in the tangential direction, I have J_θ minus $m g \sin \theta$ plus $F_m \sin \phi$. And what is the acceleration in the tangential direction?

Student: (Refer Time: 19:42).

M into $l \ddot{\theta}$ so, θ as a function of time θ , $\dot{\theta}$, $\ddot{\theta}$ can be measured in a lab setting. So, using that because these are things that cannot be directly measured, your internal forces cannot be directly measured. So, you can use a model like this to estimate the internal forces based on external measurements of the kinematics, and the known external forces known forces ok.

(Refer Slide Time: 20:32)

Angular motion

Arm has mass m_a concentrated at its centre, and is of length l
 $M \rightarrow$ mass of dumbbell

$(m_a + m) \dot{r}_{com} \hat{e}_r = m_a \left(\frac{l}{2}\right) \dot{e}_r + m l \dot{e}_r$

$r_{com} = \frac{m_a l/2 + m l}{(m_a + m)}$

$I_o = I_{cm} + r_{com}^2 (m + m_a)$

$\Sigma M_o = I_o \alpha$

TTK Center for Rehabilitation Research & Device Development (R202)
 Department of Mechanical Engineering
<https://home.jhu.ac.jp/~202>

Now, if you consider the arm to have a mass m_a , then what would you do? Here we assumed arm is weightless, arm has mass m_a , and is of length l . Then you would have let us say it acts at the middle, you have another $m_a g$ ok. Now, what would you do? Let us say we assume the mass is concentrated here ok. Then what you would do is you would basically just find the center of mass of these two masses. What would be my if I take r_{COM} ok, along e_r right that this would be m_a plus m this would be equal to.

Student: (Refer Time: 21:41).

Ma into.

Student: (Refer Time: 21:43).

L by 2 e r plus m l e r . So, my r COM would be m a l by 2 plus m l by m a plus m . So, I would just have to find the resultant center of mass, assuming these are point masses ok. We will come to a problem, where instead of assuming it as point masses we consider it a uniformly distributed mass ok. So, here it is you will just

Student: (Refer Time: 22:28).

Lump these to find the center of mass lump these two masses there, and perform the same analysis. So, instead of L you would have r COM, and the new mass of m a plus m in the previous equations, because the velocity everything you would compute for the center of mass. So, when you apply Newton's laws here, when you say $\sum F_x$ or $\sum F$ equal to m a the acceleration is for the center of mass of the system.

Student: (Refer Time: 23:04).

Inertia you will have to calculate, inertia you would have to calculate ok. But, again if you are assuming that the sum of these two point masses, so if so if you say arm has a mass m a concentrated at its center ok, then your moment of inertia will be different from if you assume its uniformly distributed, and we will do that the next we will look at a case when where the mass is uniformly distributed, because that you will take into account in your in computing the angular momentum.

Student: Ma'am, even this case when you will be substituting a point center of mass.

Student: Then also you have a movement which is about of these two masses about the center of mass which will a , which will have to add in that rate.

Yes.

Student: So, that also we have to calculate in this case.

Yes, in this case you will have to calculate the center of mass. So, the center of mass will be the center of mass about the c g of this these two about the center of mass of these two bodies.

Student: (Refer Time: 24:17).

Plus the you will use the.

Student: Parallel

Parallel axis theorem to then.

Student: (Refer Time: 24:24).

Compute it about o. You compute the I about the so if this is say the center of mass, you will compute I about the center of mass, which will basically be you know m a times this distance square then.

Student: (Refer Time: 24:44).

M times this distance square that will be your moment of inertia about the center of mass of the system. And then to compute the I about o, you will do this plus r COM square into m plus m a ok. When you compute the center of mass about the if you do the angular momentum formulation, it will kind of come in to the it will automatically come into the equation. This you need to do separately only, when we are when you are directly using sigma m naught equal to I naught alpha ok; if you use the angular momentum formulation, and then differentiate that to get it will automatically come into the equation.

(Refer Slide Time: 25:42)

Angular motion – distributed mass

Represent gymnast by rod of uniformly distributed mass m , length $2l$

Diagram shows a rod of length $2l$ pivoted at one end, rotating with angular velocity $\dot{\theta}$. The center of mass is at distance l from the pivot.

Angular momentum about pivot O :

$$\vec{H}_O = \int_0^{2l} \vec{r}_i \times m \vec{v}_i = \int_0^{2l} \vec{r}_i \times \vec{v}_i dm$$
$$\vec{H}_O = \int_0^{2l} r^2 \dot{\theta} \hat{e}_\theta \frac{m}{2l} dr$$
$$H_O = \frac{m}{2l} \int_0^{2l} r^2 \dot{\theta} dr = \frac{m \dot{\theta}}{2l} \int_0^{2l} r^2 dr = \frac{m \dot{\theta}}{2l} \left[\frac{r^3}{3} \right]_0^{2l} = \frac{4}{3} m l^2 \dot{\theta}$$

Sum of moments about pivot:

$$\Sigma M_O = \frac{dH_O}{dt} = \frac{4}{3} m l^2 \ddot{\theta}$$

Moment of inertia about center of mass C :

$$I_C = \frac{1}{12} m (2l)^2 = \frac{m l^2}{3}$$

Moment of inertia about pivot O :

$$I_O = I_C + m l^2 = \frac{m l^2}{3} + m l^2 = \frac{4}{3} m l^2$$

Parallel axis theorem

TTK Center for Rehabilitation Research & Device Development (R202)
Department of Mechanical Engineering
<https://home.illm.ac.in/2d2>

Now, let us look at the case of angular motion. So, you have a gymnast ok. Here you want to really find out, how the gymnast is going to move under the influence of gravity. So, the gymnast is holding on to the bar with the wrists ok. So, it is essentially there is no moment being supported ok, you are not resisting any moment. The pin joint cannot support cannot resist a moment. So, they are essentially going to move down under the action of gravity. And we can try to find the equations of motion of this movement ok.

In this case, let us say that you can represent the gymnast by a rod by a rod of uniformly distributed mass m , and let us say the length is $2l$ ok. Let us say, so if I look at the cg, so if this is o , I have the cg will be at l . So, let me draw the this would be m g this is point o , I have the reactions at the pin joint, which is at the wrist, and then this distance is l , this distance is l . So, the wrist acts as a pin joint about which the gymnast rotates.

And let us say the gymnast is let go from a horizontal position. So, somebody you know you have seen that in the Olympics, they will hold them in that position and then let them go. Let go from the horizontal position, they sometimes do this upside down, they have their feet into the rings. And then they will have their arms outstretched, and then move down like that ok. So, they can be modeled as a rod like this.

So, if I look at this point c representing the center of mass, I can write. So, again I can choose a coordinate system $e_r e_\theta$, and I can write r of the center of mass is $l e_r$. The velocity of the center of mass is $l \dot{\theta} e_\theta$ ok. And the acceleration of the center of mass is $l \ddot{\theta} e_\theta$ the tangential component minus $l \dot{\theta}^2 e_r$; the centripetal component and the tangential component of the radial component, and the tangential component.

So, let us formulate the equations. So, first let me try to compute the angular momentum in this case, where it is a uniformly distributed mass as opposed to a concentrated point mass that we had in the previous case. So, if I look at the angular momentum about o , you know for discrete particles we said it is $\sum r_i \times m v_i$ ok. Now this is a

Student: (Refer Time: 31:47).

Continuous rod of mass m so, we will write this as an integral, we will say this is $r \times v dm$ ok. So, I take a slice of mass dm , because the velocity in rotational motion the

velocity of every point is going to be different. So, for each dm the velocity is going to be different, it will depend on its

Student: Radial.

Radial distance from the center of rotation ok so, $r \times v \, dm$ is my angular momentum about o ok. Now, how can I express this dm , The total mass of the rod of length $2l$ rod of length $2l$ has mass m . So, if I take a small mass dm , I can write this as $m \, dr / 2l$.

Student: $2l$.

$2l$ ok so, this dm has a length dr or dr sorry I should write it as dr . This element has mass dm , and is of length dr ok. Now, I can integrate this $H_{\text{naught}} = \int_0^{2l} m \, dr / 2l \cdot r \times v$ is what is $v = r \dot{\theta} e_{\theta}$ right, and dm is $m \, dr / 2l$. So, $r \times r \dot{\theta}$ is just k .

So, I can remove the just call this $r \times r$ in vector form it is that or in scalar form because everything is along the k direction. I can write this as $\int_0^{2l} m \, dr / 2l$ is a constant, it comes outside. And I have $r^2 \dot{\theta} \, dr$. $\dot{\theta}$ is also a constant for all the points on the rod the angular velocity is the same ok.

So, I can bring $\dot{\theta}$ out as well $\int_0^{2l} r^2 \, dr$. This would be $r^3 / 3$ from 0 to $2l$. So, I get $4/3 \, m \, l^3 \dot{\theta}$ that will be my angular momentum. The sum of the moments equals dH_{naught} / dt . If I differentiate this, I get $4/3 \, m \, l^3 \ddot{\theta}$ ok. Now, let us see if whether this is your familiar $I \alpha$ ok, you have this rod of length $2l$ ok. It is moment of inertia of a uniformly distributed rod about its center of mass is $1/12$.

Student: L^2 .

M into l^2 in this case it is

Student: $2l$.

$2l$ length square ok so this gives me $m \, l^2$ by.

Student: 3.

3. Now, the moment of inertia about the point o by the parallel axis theorem equal to I_c plus m times the distance here is

Student: L square

L square ok so, I have $m l^2$ by 3 plus $m l^2$, which is 4 by 3 $m l^2$. And $\ddot{\theta}$ is my α ok. So, this shows that this is equal to $I \alpha$ ok.

(Refer Slide Time: 37:45)

So, now I can find the reactions ok, I have are you guys familiar with the kinetic diagram, have you heard that term before in a dynamics problem. If you have a rigid body ok, acted on by multiple forces ok and let us say its center of mass is here ok. And this is equivalent to this the rigid body, you have mass times the acceleration of the center of mass. And $I \alpha$ $I_c \alpha$, this is called the kinetic diagram.

The resultant of all these forces equals this; it is essentially using the neutral Euler equation. So, you have ΣF equal to $m a_c$, and ΣM about the center of mass equals $I_c \alpha$, where α is the angular acceleration. So, this is how you determine the linear and angular acceleration said that. So, using the so instead of formulating angular momentum each time, you can always use this kinetic diagram. If you know the moment of inertia about the center of mass, then you can use that to find you can use this diagram to set up your equations of motion ok. So, in this case here, we

have J , J_r , J_θ I have $m g$ those are the only forces, acting on this ok. This is equal to this is the center of mass, I have some acceleration and $I c \alpha$.

Student: (Refer Time: 40:53).

So, this I should not draw this neatly perpendicular to it, I should draw it some random m a center of mass m a center of a center of mass equals both the radial and the.

Student: Tangential.

Tangential components so, if you look at the previous slide, this is c right. We found the acceleration, can you tell me what, we found the acceleration to be we found acceleration of c as.

Student: L .

L .

Student: $\ddot{\theta}$.

$\ddot{\theta}$.

Student: e_θ .

Along e_θ minus.

Student: $L \ddot{\theta}$.

$L \ddot{\theta}$ square along e_r that is a c . And what did we find $I c$ to be.

Student: (Refer Time: 41:47).

$M b^2$

Student: $2 I$.

$2 I$ square so.

Student: (Refer Time: 41:53).

M by $m l^2$ by 3 ok; remember we have taken l as $2 l$ here that is why, usually you will see $m l^2$ by 3 for the moment of inertia about the fixed pivot.

Student: It will be change.

Yeah, that will change.

Student: Where writing of c then we will find that.

Yeah. So, now when you have the kinetic diagram, the reason it is helpful to draw the kinetic diagram is like this equations are applicable to the center of mass. Now, if I want to take moments about some other point A ok, then I have to make sure that this the moments about A equals the moments about A in the kinetic diagram. So, that way I will not miss out this $m a_c$ taking the moment of that $m a_c$ force about this other point.

Because, otherwise you will just I will show you in the next class, why that is the same as doing the I naught alpha, when he is a fixed point ok. We will stop here, because we are out of time. But, using the kinetic diagram, we will prevent you from making some of these common mistakes, when solving dynamics problems ok.

So, we will get to that in the next class.
