Stroke Adjusters and Stop Tube

- **Stroke Adjuster:** Sometimes the stroke of a piston must be externally controllable
- Periodic adjustment is accomplished with a threaded rod which can be screwed in or out of the cylinder cap as shown in Figure:
- **Stop Tube:** A stop tube is a solid, metal collar which fits over the piston rod
- A stop tube keeps the piston and rod gland bushing separated when a long-stroke cylinder is fully extended
- Since it is a bearing, a rod gland bushing is designed to take some loading when supporting the rod as it moves in and out of the cylinder
- Along with being a bearing, a rod gland bushing is also a fulcrum for the piston rod

My name is Somashekhar, course faculty for this course. Then we will see some more arrangements are there in the cylinders the Stroke adjusters and Stop tube. What is this stroke adjuster? Sometimes the stroke of a piston must be externally controlled. You will see here this is a threaded rod, lock nut, inlet outlet port, this is a barrel, inlet outlet port piston with seals and you will see here this can be moved in and out with a threaded rod with lock nut.

Meaning the periodic adjustment is accomplished with a threaded rod which can be screwed in or out of the cylinder cap as shown in the figure. This is used for stroke adjustment meaning how much it will extend. Then stop tube you will see the figure here again I have shown you the figure, here see the end is stop tube. Again inlet outlet, barrel, these are common piston, piston rod all are common here extra is a, the stop tube.

Here you will see the at the end rod gland bushings when the piston rod comes out of the, the end caps.

A stop tube, this is a stop tube is a solid, a metal collar which fits over the piston rods. A stop tube keeps the piston and the rod gland bushing separated when a long-stroke cylinder is fully extended. Since it is a bearing, a rod gland bushing is designed to take some loading when supporting the rod as it moves in and out of the cylinder. Along with being a bearing, a rod gland bushing is also a fulcrum for the piston rods.

(Refer Slide Time: 02:41).

Stroke Adjusters and Stop Tube

- If the load attached to the piston rod of a long-stroke cylinder is not rigidly guided, then at full extension, the rod will tend to teeter-totter or jack-knife at the bushing causing the excessive loading
- A stop tube in effect protects the rod gland bushing by distributing any loading at full extension between both piston and bushing
- It may be difficult to believe, but the heavy, steel rods of long-stroke cylinders sag just because of their weight as shown in Figure:
- A 0.0071 m (5/8") diameter piston rod weighs 1.356 newton per meter (1 lb. per foot) and will sag over 0.025 m (1 in.) at the centre of a 3.048 m (10 ft.) span
- On long-stroke, horizontally mounted cylinders, undesirable bearing loads are generated at the rod gland bushing because of rod sag when the rod is fully extended
- On these cylinders, a stop tube is used to separate bushing and piston when the rod is extended. This reduces the load on the rod gland bushing
- Most cylinders do not need stop tubes. To determine when a stop tube is required, or what the length of a stop tube should be, consult the cylinder manufacturers catalog

If the load attached to the piston rod of a long-stroke cylinder is not rigidly guided, then the full extension, the rod will tend to teeter-totter or a, jack-knife at the bushing causing the excessive loading. A stop tube in effect protects the rod gland bushing by distributing the any loading at full extension between both piston and bushing. It may be difficult to believe, but the heavy, steel rods of long-stroke cylinders sag just because of their weight as shown in the figure.

You will see whenever the piston rods are bigger in diameter and stroke length is very bigger outside when they will come out of the end they will sag due to the self weight. A 0.0071 meter diameter piston rod weighs these many Newton per meter and we will sag over these much meter at the centre of this span. On long-stroke, horizontally mounted cylinders,

undesirable bearing loads are generated at the rod gland bushing because of rods sag when the rod is fully extended we will see here how it is sags.

On these cylinder, a stop tube is used to separate the bushing and a piston when the rod is extended. This reduces the load on the rod gland bushing alone because it distributed over the stop tubes. Most cylinders do not need a stop tubes. To determine when a stop tube is required, or what the length of the stop tube should be, consult the cylinder manufacturers catalog. They will specify when will go for the stop tubes based on the sags and also length of the cylinder rod and diameter.

Piston-rod Buckling

- Cylinders are capable of giving very long strokes which is an essential requirement in some of the applications.
- However, if a compressive axial load is to be applied to a piston rod, it must be within the safe limit to prevent piston rod buckling.
- Owing to buckling stress, the permissible load of the piston rod should not go beyond certain maximum value as given by Euler's formula that is related to the Stroke and Piston Rod Diameter
- Euler's formula for Elastic Instability is expressed as:

Permissible buckling force (F_k) is given by

$$F_k = \frac{\pi^2 \times E \times J}{l_k^2 \times S}$$

Where E is the modulus of elasticity
 J is the moment of inertia
 S is safety factor (chosen as 5)
 l_k is the equivalent free buckling = (1 to 2) × stroke length, l

- Equivalent free buckling lengths (l_k) for different cylinder mounting arrangements are given below:

As I have told you cylinders are capable of giving a very long strokes which is an essential requirement in some of the applications. However, if the compressive axial load is to be applied to the piston rod, it must be within the safe limit to prevent the piston rod buckling.

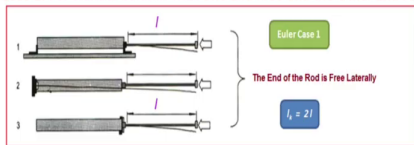

Owing to buckling stress, the permissible load of the piston rod should not go beyond the certain maximum value as given by the Euler's formula that is related to the Stroke and the Piston Rod Diameter.

The Euler's formula for elastic instability is expressed as; permissible buckling force is given by F_k equal to $\pi^2 E J$ divided by l_k^2 into S . Here E is the elastic modulus of elastic modulus and J is a moment of inertia and S is the safety factor generally chosen as a 5 and l_k is a, equivalent length for the buckling. This is 1 to 2 into stroke length l . Equivalent free buckling length l_k for a different cylinder mountings are given below here.

Different Euler Cases in Piston-rod Buckling

- Euler Case 1: For slender column with *One End Free and the Other End Fixed* $\rightarrow l_k = 2l$

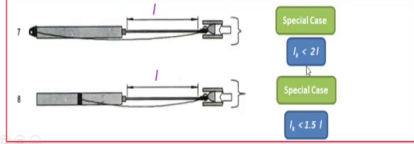

Euler Case 1
The End of the Rod is Free Laterally
 $l_k = 2l$

- Euler Case 2: For a *pin jointed slender column* $\rightarrow l_k = l$

Euler Case 2
A Worn Rod Bearing will Allow Initial Buckling as if the Rod were Pin Jointed
 $l_k = l$

- Special Cases : In *certain special cases* $\rightarrow l_k < 2l$ and $l_k < 1.5l$

Special Case
 $l_k < 2l$
Special Case
 $l_k < 1.5l$

You will see the different cases are there for the mounting, the Euler case 1 here you will see the ends of the rod is free lateral. For a slender column with one end free and the other end

fixed, l_k free buckling length l_k equal to $2l$, l is a stroke complete stroke. Euler case l_k equal to $2l$.

The Euler case 2 meaning for a pin jointed slender column. Pin jointed slender column l_k equal to l . Meaning here you will see the worn rod bearings will allow the initial buckling as if the rod were pin jointed, in such cases you will use l_k equal to l meaning equal to stroke length.

The special cases, you will see the special cases in a certain special cases the l_k is less than $2l$ and l_k is less than 1.5 times l . These are the special cases in both the cases you will see. The effective length l_k is how to take as an empirical value when they will mount like this.

Various Types of Cylinder Mountings

- Various types of cylinder mountings are in existence, among which are flange, trunnion, side lug and side tapered, clevis, tie rod, and bolt mounting are most common.
- This permits versatility in the anchoring of cylinders.
- Figure shows the various types of cylinder mountings
- The rod ends are usually threaded so that they can be attached directly to the load, a clevis, a yoke, or some other mating device

 Foot and Centerline Lug Mounts	 Rectangular Flange Mount	 Square Flange mount
 Trunnion Mount	 Clevis Mount	 Flush Side Mount
 Intermediate Trunnion Mount	 Extended Tie Rod Mount	 Double Rod End Mount

The various types of cylinder mountings are in existence among which are a flange, trunnion, side lug and a side tapered, clevis, tie rod and a bolt mounting are most common. I will show you some of the cylinder mounting here these are permits the versatility in the anchoring of the cylinders.

Figure shows the various types of cylinder mountings. The rod ends are usually threaded, so that they can be attached directly to the loads, here or a clevis or a yoke are some other mating device they are used here. You will see friends here the different types of cylinder mountings.

Please note here it is a foot and central line lug mounting here, you will see the rectangular, flange mounting here you will t square flange mounting, here a trunnion mounting, here you will see the clevis mounting flush side mounting and intermediate trunnion mounting, intermediate trunnion mounting, the extended tie rods mounting tie rods, a double rod end mounting.

There are various types of mountings are there when you are installing the cylinder be careful for the mounting based on the pressure requirement movement working cycles all these are very very important.

Mechanical Linkages for Different Mechanical Motions

- Typical mechanical linkages that can be combined with cylinders to transform a linear motion into either an oscillating or rotary motion are shown below:
- In addition, linkages can also be employed to increase or decrease the effective leverage and stroke of a cylinder

Then we will discuss some of the mechanical linkages for different mechanical motions. Typical mechanical linkages that can be combined with cylinders to transfer a linear motion into either an oscillatory or rotary motion as shown in the figure below. In addition, the linkages can also be employed to increase or decrease the effective leverage and a stroke of the cylinder.

See here, the different types of linkages are I have shown here along with the cylinders, these are all called a cylinders and these are the linkages to get the different motions when the cylinder will move in the same direction up and down or a vertical, but we will get to the different forms of motion using the various linkages.

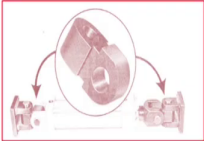

You will see here the first class linkage. Meaning cylinder will move up and down this is pinned here you will get movement here.

Similarly second class arrangement see the arrangement fixed here, third class arrangement, when it will move how it will move. You see the arrangement the toggle, straight line thrust reducer, like this there are different types of linkages are used along with the cylinders to get the required motions. But cylinder motion is only the linear motion, but you will get the any types of motion you will see here based on the, a linkages how we are using.

(Refer Slide Time: 12:01)

Mechanical Linkages for Different Mechanical Motions

- Much effort has been made by manufacturers of hydraulic cylinders to **reduce or eliminate the side loading of cylinders created as a result of misalignment**
- It is **almost impossible to achieve perfect alignment** even though the alignment of a hydraulic cylinder has a direct bearing on its life
- A **universal alignment mounting accessory** designed to reduce misalignment problems is illustrated in Figure:

- By using **one of these accessory components and a mating clevis at each end of the cylinder** the following benefits are obtained
 1. Freer range of mounting positions
 2. Reduced cylinder binding and side loading
 3. Allowance for universal swivel
 4. Reduced bearing and tube wear
 5. Elimination of piston blow-by caused by misalignment

Much effort has been made by the manufacturer of hydraulic cylinder to reduce or eliminate the side loading of the cylinder created as a result of the misalignment. It is almost impossible to achieve the perfect alignment even though the arrangements of a hydraulic cylinders has a direct bearing on its life. A universal alignment mounting, here you will see this is a cylinder

two sides. A universal alignment mounting accessory designed to reduce the misalignment problem is illustrated here the two sides.

By using one of these accessory components and a matching clevis at each end of the cylinder the following benefits can be achieved. Freer range of mounting positions, reduced cylinder binding and side loading, allowance for universal swivel, reduced the bearing and a tube wear, elimination of piston blow-by caused by the misalignment.

Types of Cylinder Loads

- Cylinders can be used in an unlimited number of applications to move various types of loads
- But in general, a load which is pushed by a piston rod is termed a thrust load or push load
- A load which is pulled by a piston rod is called a tension load or pull load
- These load are shown below:

Thrust Load or Push Load

Tension Load or Pull Load

Now, quickly we will see the different types of cylinder loads. Cylinders can be used in an unlimited number of application to move the various types of loads. But in general, a load which is pushed by the piston rod is termed as a thrust load or a push load. A load which is pulled by a piston rod is called a tension load or a pull load. You will see the cylinder load

two types; push type and a pull type push type is also known as a thrust load pull type is also known as a tension load.

Here I have shown you here friends these loads. You will see the vertically mounted. What I am using the fluid pressure is used to push this, meaning the thrust load here. Here you will see arrangement the fluid pressure is used to pull, meaning the tension load or a pull load. Please understand the meaning.

Here also we will see the fluid pressure is used to push this; meaning it is a push loads meaning cylinder will extend and push the load here. The cylinder will retract here the, what I am using fluid pressure is used to pull it the tension load. Please understand these things.
