Lecture - 13
Finite Difference Approximation of Second Order Derivatives-2

Welcome back to the next lecture in module 3 on finite difference method. We will continue from where we left in the first lecture on second order derivative. So we are going to focus on finite difference approximation of second order derivatives in this lecture. What we discussed in lecture 3, so previous lecture was we discussed approximation approaches.

(Refer Slide Time: 00:52)

A blue rectangular slide with white text. The title 'Recapitulation of Lecture III.3' is at the top. Below it, the text 'In previous lecture, we discussed:' is followed by two bullet points, each marked with a red diamond icon. The first bullet point is 'Approximation Approaches' and the second is 'Approximations based on Taylor Series Expansion'. At the bottom, the text 'for FD approximation of Second Order Derivatives.' is displayed.

Recapitulation of Lecture III.3

In previous lecture, we discussed:

- ❖ Approximation Approaches
- ❖ Approximations based on Taylor Series Expansion

for FD approximation of Second Order Derivatives.

And we derived approximations based on Taylor series expansion for finite difference approximation of second order derivative. So we are going to continue the same part, that is we would derive finite difference approximation of second order derivatives.

(Refer Slide Time: 01:13)

LECTURE OUTLINE

- ❖ Approximations based on Taylor Series Expansion
 - ❖ **General Procedure on Uniform Grids**
- ❖ Polynomial Fitting
- ❖ Approximation of 2nd Order Derivative in Scalar Transport Equation

We will continue our approximations based on Taylor series expansion, particularly the one based on general procedure on uniform grids, then we will take up how do we obtain finite difference approximations based on polynomial fitting, and then we would try and obtain approximation of second order derivative in scalar transport equation. So now let us have a relook at a general procedure, which we outlined earlier.

(Refer Slide Time: 01:48)

GENERAL PROCEDURE BASED ON TAYLOR SERIES EXPANSION

On uniform grid, difference approximation for second order derivative can be expressed as (Chung, 2010)

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i \approx \frac{af_i + bf_{i-1} + cf_{i+1} + df_{i-2} + ef_{i+2} + \dots}{\Delta x^2}$$

Coefficients a, b, c, d, \dots can be determined from Taylor series expansions for function values on RHS.

That on uniform grid, difference approximation for second order derivative can be expressed as $\frac{\partial^2 f}{\partial x^2}_i$, this is approximately $= a*f_i + b*f_{i-1} + c*f_{i+1} + d*f_{i-2} + e*f_{i+2}$ so on Δx^2 and these coefficients a, b, c, d , can be determined from Taylor series expansions for

function values f_i , f_{i-1} , f_{i+1} and so on. We will substitute them on the right hand side and try and equate the terms appearing on both the sides and thereafter you will get system equation.

From which we can determine a, b, c, d, etc. Let us take one or 2 examples of this approach, which is proposed by Chung in 2010. Now first thing we will take up is three-point central difference formula.

(Refer Slide Time: 02:50)

**... GENERAL PROCEDURE BASED ON
TAYLOR SERIES EXPANSION**

3- Point Central Difference Formula

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i \approx \frac{af_i + bf_{i-1} + cf_{i+1}}{\Delta x^2}$$

Use of Taylor series expansion gives $a=-2 \quad b=c=1$

Therefore,

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i = \frac{f_{i+1} + f_{i-1} - 2f_i}{(\Delta x)^2} - \frac{\Delta x^2}{12} \left(\frac{\partial^4 f}{\partial x^4} \right)_i, \quad \text{TE} \approx O(\Delta x^2)$$

So this is our general formula $\frac{\partial^2 f}{\partial x^2} \approx \frac{af_i + bf_{i-1} + cf_{i+1}}{\Delta x^2}$ and using this formula, let us find out the values of a, b, and c involved in this approximation using Taylor series expansion.

(Refer Slide Time: 03:17)

3-Point Central Difference
Scheme for 2nd Order Derivative
(Uniform grid: Δx)

$$\left(\frac{\partial^2 f}{\partial x^2}\right)_i \approx \frac{a f_i + b f_{i-1} + c f_{i+1}}{\Delta x^2}$$

$$\begin{aligned} &= \frac{a f_i + b f_{i-1} + c f_{i+1}}{a f_i + b \left\{ f_i - \Delta x \left(\frac{\partial f}{\partial x}\right)_i + \frac{\Delta x^2}{2} \left(\frac{\partial^2 f}{\partial x^2}\right)_i - \frac{\Delta x^3}{6} \left(\frac{\partial^3 f}{\partial x^3}\right)_i + \frac{\Delta x^4}{24} \left(\frac{\partial^4 f}{\partial x^4}\right)_i + H \right\} + c \left\{ f_i + \Delta x \left(\frac{\partial f}{\partial x}\right)_i + \frac{\Delta x^2}{2} \left(\frac{\partial^2 f}{\partial x^2}\right)_i + \frac{\Delta x^3}{6} \left(\frac{\partial^3 f}{\partial x^3}\right)_i + \dots \right\}} \\ &= \frac{(a+b+c) f_i + (-b+c) \Delta x \left(\frac{\partial f}{\partial x}\right)_i + \frac{\Delta x^2}{2} (b+c) \left(\frac{\partial^2 f}{\partial x^2}\right)_i + \frac{\Delta x^3}{6} (-b+c) \left(\frac{\partial^3 f}{\partial x^3}\right)_i + \frac{\Delta x^4}{24} (b+c) \left(\frac{\partial^4 f}{\partial x^4}\right)_i + H}{\Delta x^2} \end{aligned}$$

So we want to find out a three-point central difference approximation or central difference scheme for second order derivative. The grid is supposed to be uniform and let us use symbol delta x to denote our grid size. So let us rewrite our formula or formula of $\frac{\partial^2 f}{\partial x^2}$ at the grid point i approximately = $\frac{a f_i + b f_{i-1} + c f_{i+1}}{\Delta x^2}$. So basically what we have is, we have taken 2 points in the neighborhood of our grid point i.

So grid point i, we have taken the grid point i+1 to the right of it and grid point i-1 to the left of it. Now let us substitute on this formula the values of f_{i-1} and f_{i+1} using Taylor series expansion around point x_i . So if you do that, let us have a look at the numerator, that is $a f_i + b f_{i-1} + c f_{i+1}$. The first term remains as such $a f_i$. Now for $b f_{i-1}$, now let us use Taylor series expansion. So it would be $f_i - \Delta x \left(\frac{\partial f}{\partial x}\right)_i + \frac{\Delta x^2}{2} \left(\frac{\partial^2 f}{\partial x^2}\right)_i - \frac{\Delta x^3}{6} \left(\frac{\partial^3 f}{\partial x^3}\right)_i + \frac{\Delta x^4}{24} \left(\frac{\partial^4 f}{\partial x^4}\right)_i + \dots$

So this completes our expansion for value of f_{i-1} in terms of f_i . Now c * the expansion for f_{i+1} . This becomes $f_i + \Delta x \left(\frac{\partial f}{\partial x}\right)_i + \frac{\Delta x^2}{2} \left(\frac{\partial^2 f}{\partial x^2}\right)_i + \frac{\Delta x^3}{6} \left(\frac{\partial^3 f}{\partial x^3}\right)_i + \frac{\Delta x^4}{24} \left(\frac{\partial^4 f}{\partial x^4}\right)_i + \dots$. Now let us collect the like terms like the ones which involve function values or first derivative, second derivative and so on. Let us collect them together.

So we have got three terms involving function values, $a f_i$, $b \cdot f_i$, and $c \cdot f_i$. So we will get $a+b+c \cdot f_i$. Now let us next collect the multipliers of the first derivative. So we get $-b$ coming from the expansion of f_{i-1} and $-b+c \cdot \Delta x \frac{df}{dx}$ at $i+\Delta x^2/2$ $b+c \frac{d^2 f}{dx^2}$ at $i+\Delta x^3/6$ we will get $(-b+c \frac{d^3 f}{dx^3})$ at $i+\Delta x$ to the power $4/24$ $b+c \frac{d^4 f}{dx^4}$ at i higher order terms.

So now let us substitute this value which we have obtained for $a f_i + b f_{i-1} + c f_{i+1}$ into our generic formula, we have started off. We will call this equation 1, expansion of which we got as 2, so substitute 2 into equation 1.

(Refer Slide Time: 10:13)

(2)

Substitute (2) into eqn. (1):

$$\left(\frac{\partial^2 f}{\partial x^2}\right)_i = \frac{(a+b+c)}{\Delta x^2} f_i + \frac{(-b+c)}{\Delta x} \left(\frac{\partial f}{\partial x}\right)_i + \frac{(b+c)}{2} \left(\frac{\partial^2 f}{\partial x^2}\right)_i + \frac{\Delta x}{6} (-b+c) \left(\frac{\partial^3 f}{\partial x^3}\right)_i + \frac{\Delta x^2}{24} (b+c) \left(\frac{\partial^4 f}{\partial x^4}\right)_i + H$$

Comparing the coefficients on two sides of terms involving f_i , $\left(\frac{\partial f}{\partial x}\right)_i$, $\left(\frac{\partial^2 f}{\partial x^2}\right)_i$, ...

$$\begin{aligned} a+b+c &= 0 \implies a = -b-c = -2 \\ -b+c &= 0 \implies 2c = 2 \implies c = 1 \\ b+c &= 2 \implies b = c = 1 \end{aligned}$$

$$TE = \frac{\Delta x^4}{12} \left(\frac{\partial^4 f}{\partial x^4}\right)_i + H$$

$TE \sim O(\Delta x^2)$

So what we will get, $\frac{d^2 f}{dx^2}$. This is what we get on the right hand side. This is $= a+b+c/\Delta x^2 \cdot f$ of $i+(-b+c)/\Delta x \frac{df}{dx}$ at $i+b+c/2 \frac{d^2 f}{dx^2}$ at $i+\Delta x/6$ $b+c \frac{d^3 f}{dx^3}$ at $i+\Delta x^2/24$ $b+c \frac{d^4 f}{dx^4}$ + higher order terms. So now let us compare the coefficients of the function values derivatives of different orders, which we have got in left hand side and right hand side.

So on the left hand side we do not have any term, which contains f_i , we do not have any term containing first derivative or third derivative and so on. So if you compare the coefficients on 2 sides of terms involving $f_i \frac{df}{dx}$ of $i \frac{d^2 f}{dx^2}$ i and so on. What do we get. We get

$a+b+c=0$. That is what we get. The coefficient of f_i on the left hand side. There is no term on f_i , so its coefficient is 0.

On the right hand side, we have got $a+b+c/x^2$, so this should be set to 0, so we get this equation in terms of a , b , and c $a+b+c=0$. Similarly, this node term which contains the first derivative on the left hand side, but we have got one term $-b+c/\Delta x \frac{df}{dx}$ in the right hand side, so its coefficient must vanish as well. So we get $-b+c=0$. We got three unknowns. We need one more equation. Now let us compare the coefficients of the second derivative.

The coefficient of second derivative $\frac{d^2f}{dx^2}$ is the one on the left hand side. Its coefficient on the right hand side is $b+c/2$. So if we equate these 2, we get $b+c=2$. From these equations if you just add the last 2 equations, we get $2c=2$, which implies $c=1$ and we can solve for b from second equation, $b=c$. We get $b=c=1$, substitute these values of b and c in the first equation, so this equation will give us the value of a , $a=-b-c$.

So thereby we get the value of -2 . So let us summarize it on the slide. So by Taylor series expansion, we have got $a=-2$, $b=c=1$. So therefore we get pretty simple form for the second order derivative $\frac{d^2f}{dx^2} = \frac{1}{\Delta x^2} (f_{i+1} + f_{i-1} - 2f_i)$. What happens to a truncation error. So truncation error, let us see on the right hand side the terms, which involve the higher order derivatives.

The term containing the third derivatives $-b+c$, b and c are equal, so this term vanishes. So our truncation error is basically $\Delta x^2/12$, we substitute for b and c here, so $b+c$ we get 2, $2/24$ that gives us $1/12$. So $\Delta x^2/12 \frac{d^3f}{dx^3}$. So we can clearly say that this central difference approximation has got a truncation error of the order 2 of Δx^2 that is it is a second order accurate scheme.

(Refer Slide Time: 17:10)

... GENERAL PROCEDURE BASED ON TAYLOR SERIES EXPANSION

3- Point Backward Difference Formula

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i = \frac{f_i - 2f_{i-1} + f_{i-2}}{(\Delta x)^2} + \Delta x \left(\frac{\partial^3 f}{\partial x^3} \right)_i$$

5- Point Central Difference Formula

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i = \frac{-30f_i + 16(f_{i-1} + f_{i+1}) - (f_{i-2} + f_{i+2})}{12\Delta x^2} + O(\Delta x^4)$$

We can also find out a one side formula of 3-point backward difference formula by taking the values at point f_i , f_{i-1} and f_{i-2} and in this case, our truncation error involves the terms of order Δx . So this 3-point one-sided difference formula, which we can get using this general procedure has got a first order accuracy. We can also obtain higher than second order formula using this Taylor series expansion. So let us take a 5-point central difference formula.

We will do part of the derivation and part will be left to you as an exercise.

(Refer Slide Time: 18:01)

$$\begin{aligned} \left(\frac{\partial^2 f}{\partial x^2} \right)_i &\approx \frac{1}{\Delta x^2} \left[f_i(a+b+c+d+e) \right. \\ &\quad + \left(\frac{\partial f}{\partial x} \right)_i \Delta x(-b+c-2d+2e) \\ &\quad + \left(\frac{\partial^2 f}{\partial x^2} \right)_i \frac{\Delta x^2}{2}(b+c+4d+4e) \\ &\quad + \left(\frac{\partial^3 f}{\partial x^3} \right)_i \frac{\Delta x^3}{6}(-b+c-8d+8e) \\ &\quad + \left(\frac{\partial^4 f}{\partial x^4} \right)_i \frac{\Delta x^4}{24}(b+c+16d+16e) \\ &\quad + \left(\frac{\partial^5 f}{\partial x^5} \right)_i \frac{\Delta x^5}{120}(-b+c-32d+32e) \\ &\quad \left. + \left(\frac{\partial^6 f}{\partial x^6} \right)_i \frac{\Delta x^6}{720}(b+c+64d+64e) + H \right] \end{aligned}$$

$$\begin{aligned} a+b+c+d+e &= 0 & (1) \\ -b+c-2d+2e &= 0 & (2) \\ b+c+4d+4e &= 2 & (3) \\ -b+c-8d+8e &= 0 & (4) \\ b+c+16d+16e &= 0 & (5) \end{aligned}$$

So we want to find out a 5-point central difference formula for second order derivative. This higher order formula is sometimes used in the finite difference course, which require extremely

accurate finite difference approximations. So our first point would be our central point that is i -th grid point. We will take 2 points on each side. That is grid point $i+1$ and $i+2$ on the right hand side of point i and $i-1$ and $i-2$ to the left.

So difference scheme or difference formula, we can express as $a f_i + b f_{i-1} + c f_{i+1} + d f_{i-2} + e f_{i+2} / \Delta x^2$. So we have got five unknown coefficients, which we must determine using Taylor series expansion and let us do that straight away by putting expanded forms for f_{i-1} , f_{i+1} , f_{i-2} and f_{i+2} on the right hand sides. We can write $1/\Delta x^2$, now let us try and collect similar terms, the terms which are going to multiply f_i .

We will get a constant term f_i in all these remaining 4 expansions, we will get f_i would be multiplied by $a+b+c+d+e$. Now next we will have terms collecting coefficient of $\Delta f / \Delta x$, so what do we get. The first term $a f_i$, that will remain as such. We will get this $\Delta f / \Delta x$ occurring in the expansions of f_{i-1} , f_{i+1} , f_{i-2} , and f_{i+2} . So let us take what do we get from expansion of f_{i-1} . From here we will get simply a term containing Δx .

So here we will have, let us take Δx common. So from expansion of f_{i-1} , we will get the contribution $-b$. From the expansion of f_{i+1} we have the coefficient $\Delta x * c$, Δx we have taken out, so we get $+c$, f_{i-2} . Now here the difference is $-2 \Delta x$, so we get $-2d$ and similarly the contribution coming from the expansion of f_{i+2} $2e$. So that completes our collection of the terms from expansion, which have $\Delta f / \Delta x$.

Now let us collect the terms containing second order derivative $\Delta^2 f / \Delta x^2$ at i . Let us take this $\Delta x^2 / 2$ outside. So from expansion of f_{i-1} , we will simply get $+b$, from f_{i+1} expansion, we get the contribution c , from f_{i-2} and f_{i+2} , we have got $2 \Delta x^2$ whole square. So we will get $4d+4e$. Next, the third order derivative. Here let us take $\Delta x^3 / 6$ outside. So we get from expansion of f_{i-1} , the contribution would be $-b f_{i+1} + c$.

From f_{i-2} , we will get $2 \Delta x^3 * d$ that is $8d f_{i+2} - 8e$. Similarly $\Delta^4 f / \Delta x^4$ to the power $4i$, let us take $\Delta x^4 / 24$ factorial that is 24 outside. So we would be left with $b+c+16d+16e$. Next our fifth order derivative, $\Delta^5 f / \Delta x^5$ Δx to the power $5/120$ is taken as

common, so we get $-b+c-32d+32e$. Let us write one more term $\frac{6f}{\Delta x^6}$ of i , common multiply Δx to the power of 6/720 $b+c+64d+64e$ and +remaining higher order terms.

Now to obtain the equations for a, b, c, d , now let us compare the terms on the LHS and RHS of this equation. Left hand side we have got only the second order derivative term. So coefficients of rest of the terms as a function value itself or first order derivative, third order derivative, fourth order, fifth order, and so on. They can be all set to 0.

So we need five equations. First let us compare the coefficients of f_i on both the sides. So this gives us $a+b+c+d+e=0$. Let us call this equation as 1. Second equation we can get by comparing the coefficient of $\frac{f}{\Delta x}$ in both LHS and RHS. In LHS, we have got value 0. So RHS we will get $-b+c-2d+2e=0$. Next compare the coefficients of $\frac{2f}{\Delta x^2}$. So this will give us $b+c+4d+4e=2$. Now I have got 3 equations. We need 2 more.

So let us next compare the coefficient of $\frac{f}{\Delta x^3}$ of both the sides. So we will get $-b+c-8d+8e=0$ and next equation we can get by comparing coefficient of $\frac{4f}{\Delta x^4}$. So that gives us $b+c+16d+16e=0$. Now we have got 5 equations and 5 unknowns a, b, c, d, e and you can solve these equations that I would leave as an exercise. I will just give you the summary of the results that if you solve these equations what do we get. We get the values of a, b, c, d, e .

(Refer Slide Time: 28:32)

... GENERAL PROCEDURE BASED ON TAYLOR SERIES EXPANSION

3- Point Backward Difference Formula

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i = \frac{f_i - 2f_{i-1} + f_{i-2}}{(\Delta x)^2} + \Delta x \left(\frac{\partial^3 f}{\partial x^3} \right)_i$$

5- Point Central Difference Formula

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i = \frac{-30f_i + 16(f_{i-1} + f_{i+1}) - (f_{i-2} + f_{i+2})}{12\Delta x^2} + O(\Delta x^4)$$

So we get on solving these equations, we get $a = -5/2$, $b = c$, b and c they are both equal, that is $4/3$. Similarly d and e are also equal $d = e = -1/12$. We can substitute these values and you can make few observations. By substituting the value, we get the final formula and the values of d and e are equal, so that will tell us that the coefficients, which multiplies $\frac{\partial^5 f}{\partial x^5}$ that becomes 0. So the leading coefficient and truncation error would be given by the multiply of $\frac{\partial^6 f}{\partial x^6}$.

So our truncation error for this scheme that is $\frac{\partial^6 f}{\partial x^6} \frac{\Delta x^6}{6!} b + c + 64d + 64e \Delta x$ to the power of $4/720$. Substitute the values of b, c, d, e and so on to get actual values of truncation error. You can clearly see this order of truncation error is Δx to the power of 4. So now let us have a look at the summary of this formula, which we derived. This 5-point difference formula, $\frac{\partial^2 f}{\partial x^2} = \frac{-30f_i + 16f_{i-1} + f_{i+1} - f_{i-2} + f_{i+2}}{12 \Delta x^2}$.

And the truncation error is of the order Δx to the power of 4. So this scheme is fourth order accurate. So now here we would put a stop to our approach or derivations based on Taylor series expansion. Let us have a look at the next scheme that is obtaining approximation of derivatives by polynomial fitting.

(Refer Slide Time: 31:30)

APPROXIMATION OF DERIVATIVES BY POLYNOMIAL FITTING

A generic function $f(x)$ can be approximated by a polynomial as

$$f(x) = a_0 + a_1(x - x_i) + a_2(x - x_i)^2 + \dots + a_n(x - x_i)^n$$

Coefficients a 's are obtained by fitting the interpolation curve to function values at appropriate number of points.

Derivatives at point $x = x_i$ are given by

$$\left(\frac{\partial f}{\partial x}\right)_i = a_1, \left(\frac{\partial^2 f}{\partial x^2}\right)_i = 2a_2, \left(\frac{\partial^3 f}{\partial x^3}\right)_i = 6a_3, \dots$$

We have already seen this expansion earlier that a generic function $f(x)$ can be approximated by a polynomial as $f(x) = a_0 + a_1(x - x_i) + a_2(x - x_i)^2 + \dots$ so on an $(x - x_i)$ to the power n . We have taken in terms of $x - x_i$ so that we can easily obtain the expression for the derivative and $x = x_i$ and these

coefficients a_0 , a_1 and so on, we would obtain by fitting the interpolation curve. This is given by this polynomial to the function values at appropriate number of points.

And if you want to find derivatives, just simply differentiate this polynomial, so they get $\frac{df}{dx}$ this coefficient a_1 . The second order derivative is given by $2*a_2$, third order derivative $\frac{d^3f}{dx^3}$ is given by $6*a_3$ and so on. So we have already used this approach to derive few formulae for first order derivative. Now let us try and do one more and one derivation for our second order derivative.

In fact as part of the derivation, we can also obtain a formula or higher order formula for first order derivative as well.

(Refer Slide Time: 33:02)

**... APPROXIMATION OF FIRST ORDER
DERIVATIVES BY POLYNOMIAL
FITTING**

Five point finite difference approximation
obtained by fitting a 4th degree polynomial

$$f(x) \approx a_0 + a_1(x - x_i) + a_2(x - x_i)^2 + a_3(x - x_i)^3 + a_4(x - x_i)^4$$

at grid points $i-2$, $i-1$, i , $i+1$ and $i+2$:

$$\left(\frac{\partial^2 f}{\partial x^2} \right)_i = 2a_2 = \frac{-f_{i-2} + 16f_{i-1} - 30f_i + 16f_{i+1} - f_{i+2}}{12\Delta x^2}$$

So what we would try to attempt is let us find out 5-point finite difference approximation by fitting a fourth degree polynomial. So fourth degree polynomial is given by $f(x)$ is $a_0 + a_1*x - x_i + a_2*x - x_i^2 + a_3*x - x_i^3 + a_4*x - x_i^4$. In this fourth order polynomial, we have got a_0 , a_1 , a_2 , a_3 , and a_4 , we have got a total of 5 unknown numerical coefficients, so that is why we need to equate this polynomial at 5 grid points to determine the values of a_0 , a_1 , a_2 and so on.

For a central difference formula, let us take the grid points as $i-2$, $i-1$, i , $i+1$ and $i+2$. Let us get back to the board and try to derive our approximation based on fourth order polynomial fit.

(Refer Slide Time: 34:15)

$$\begin{aligned}
 &\text{Add Eq. (5) and Eq. (6):} \\
 &f_{i+2} + f_{i-2} = 2f_i + (8\Delta x^2) a_2 + (32\Delta x^4) a_4 \quad (7) \\
 &\text{Add Eq. (3) and Eq. (4):} \\
 &f_{i+1} + f_{i-1} = 2f_i + 2\Delta x^2 a_2 + 2\Delta x^4 a_4 \quad (8) \\
 &(8) \times 4 \Rightarrow 16(f_{i+1} + f_{i-1}) = 32f_i + 32\Delta x^2 a_2 + 32\Delta x^4 a_4 \quad (9) \\
 &(9) - (7): 16(f_{i+1} + f_{i-1}) = 30f_i + 24\Delta x^2 a_2 \\
 &\quad = (f_{i+2} + f_{i-2}) \\
 &\Rightarrow 2a_2 = \frac{16(f_{i+1} + f_{i-1}) - (f_{i+2} + f_{i-2}) - 30f_i}{12\Delta x^2} \\
 &\text{ie } \left(\frac{\partial^2 f}{\partial x^2} \right)_i \approx \frac{-f_{i-2} + 16(f_{i-1} + f_{i+1}) - 30f_i - f_{i+2}}{12\Delta x^2}
 \end{aligned}$$

So polynomial fitting approach, first let us note down our grid points i , $i+1$, $i+2$, $i-1$, $i-2$. For the sake of simplicity of derivation, let us assume a uniform grid. So let us take an uniform grid and our grid spacing is Δx , so with reference to point i the spacing between i and $i+1$, this would be Δx . Similarly the difference between i and $i+2$ that would become $2\Delta x$ and so on.

So if we choose our coordinate frame, centered at the grid location x_i , we can obtain the values for the differences for these different points for substitution in our polynomial. Now let us write our fourth order polynomial fit, polynomial interpolation for function $f(x)$. So $f(x) = a_0 + a_1(x - x_i) + a_2(x - x_i)^2 + a_3(x - x_i)^3 + a_4(x - x_i)^4$. So if taken a fourth order polynomial, now let us equation this interpolation to the function values at points i , $i+1$, $i-1$, $i+2$, and $i-2$.

So let us do it 1 by 1. First by equating the function values at point x_i , $f(x_i)$ is given by f_i and that gives us a_0 . So straightly we have got the value for a_0 , which we can substitute in further expressions. Now f of $i+1$ that will give us f_{i+1} $f_{i+1} = f_i + a_1\Delta x + a_2\Delta x^2 + a_3\Delta x^3 + a_4\Delta x^4$. Interpolation equation 1, 2, let us call this equation as 3. Function value at $f_{i-1} = f_i$.

Now x is x_{i-1} , so $x_{i-1} - x$ square that will give us $-\Delta x$, so we get $a_1 * -\Delta x$, this $-$ sign comes here $+a_2 * -\Delta x$ square, which simply gives us $+\Delta x$ square $-a_3 * \Delta x$ cube $+a_4 * \Delta x$ 4. Let us call this equation as 4. Next equate the values at point $i+2$. So $f(i+2) = f_i + 2 \Delta x * a_1$. I have got $2 \Delta x$ as $x - x_i$, so this square term would give us $4 \Delta x$ square $* a_2 + 8 \Delta x$ cube $* a_3 + 16 \Delta x$ 4 $* a_4$. Let us call this equation as 5, $f(i-2)$.

Now $x - x_i$ in this case would become $-2 \Delta x$, so $f_{i-2} \Delta x * a_1 + 4 \Delta x$ square $* a_2 - 8 \Delta x$ cube $* a_3 + 64 \Delta x$ 4 $* a_4$. Let us call this equation as 6. Now we have got the required number of equations. The equation 2 gives us the value of coefficient a_0 . We are interested in finding out the values of coefficients a_1 and a_2 , a_2 will give us the second derivative and a_1 will give us the approximation for first order derivative.

Now let us have a look at equations 5 and 6, let us add them together. So what we get $f(i+2) + f_{i-2} = 2f_i$, see this a_1 and a_3 , these 2 terms would vanish so we get 4 and $48 \Delta x$ square $* a_2 + 32 \Delta x$ to the power $4 * a_4$. Similarly if we add equations 3 and 4, the ones in terms of f_{i+1} and f_{i-1} , this is equation 7. So add equations 3 and 4. So this addition will again eliminate a_1 and a_3 terms, so we get yet another equation in terms of a_2 and a_4 .

So we will get $f(i+1) + f(i-1) = 2f_i + 2 \Delta x$ square $* a_2 + 2 \Delta x$ to the power of $4 * a_4$. So now this 7 and 8, these 2 equations involve only coefficients a_2 and a_4 . So we can eliminate a_4 , thereby obtain a value for a_2 . So to eliminate a_4 , let us multiply equation 8 by 16. So equation $8 * 16$ that will give us $16 * f(i+1) + f(i-1) = 32 f_i + 32 \Delta x$ square $a_2 + 32 \Delta x$ to the power of $4 a_4$. Now let us subtract equation 7 from equation 9, $9 - 7$.

If you do that we would be able to eliminate a_4 , $16 f(i+1) + f(i-1) = 30 f_i + 24 \Delta x$ square a_2 and on the left hand side we will have 8 and the term $-f_{i+2} + f_{i-2}$. So now let us rearrange and thus write down the value of $2a_2$, so $2a_2$ will become $16 f(i+1) + f_{i-1} - f_{i+2} + f_{i-2} - 30 f_i / 12 \Delta x$ square and this is what we are looking for because twice of a_2 gives us the second derivative, so that is $\frac{d^2 f}{dx^2}$ at i . Now we have got an approximation for it.

Now let us write the terms in index order $-f_{i-2} + 16f_{i-1} + f_{i+1} - 30f_i - f_{i+2}/12 \Delta x^2$. Now let us summarize this result on our slide. That is what we get $\frac{\partial^2 f}{\partial x^2} \approx$ twice of a_2 , which is $-f_{i-2} + 16f_{i-1} - 30f_i + 16f_{i+1} - f_{i+2}/12 \Delta x^2$. Now these equations which we have derived or which we have written for these coefficients a_1 , a_2 , a_3 , and a_4 , you can also find out and I would leave as an exercise.

(Refer Slide Time: 48:01)

- Exercise
- ① Solve the preceding equations for $a_1 \approx \left(\frac{\partial f}{\partial x}\right)_i$
 - ② Find out truncation error for the approximations obtained for $\left(\frac{\partial f}{\partial x}\right)_i$ and $\left(\frac{\partial^2 f}{\partial x^2}\right)_i$.

This is an exercise, solve the preceding equations for a_1 and if you solve for a_1 that is an approximation for $\frac{\partial f}{\partial x}$. So this is one exercise and the second exercise, which I would like you to do is find out truncation error for the approximations, which we have obtained for $\frac{\partial f}{\partial x}$ and $\frac{\partial^2 f}{\partial x^2}$. Use Taylor series expansions to find out your results. Now there is something which I would like to note here, which you can try and verify from your results on truncation error.

... APPROXIMATION OF SECOND ORDER DERIVATIVES BY POLYNOMIAL FITTING

- ❖ In general, truncation error of the approximation to second order derivative obtained by fitting a polynomial of degree n is of order $(n-1)$.
- ❖ One order is gained (i.e., truncation error is of order n) if grid spacing is uniform and an even-order polynomial is used.

We have already made similar comments on the approximation of first order derivative by polynomial fitting and what happens in the case of second order derivatives. In general truncation error of the approximation to second order derivative obtained by fitting a polynomial of degree n is of order $n-1$. However, one order is gained that is truncation error is of order n . If grid spacing is uniform, this is the first condition and an even order polynomial is used.

So in just discussed example, we had taken uniform grid spacing and polynomial of order 4. So this observation says that you truncation error should be of order 4. Now please verify from your derivations. Today, in this lecture, we stop here as for the approximation of second order derivatives is concerned and in the next lecture, we will have further look at finite difference approximations for the second order derivative occurring in generic transport equation and for mixed derivatives.

We will also take up the case of multidimensional problems, so how do we obtain the approximation for the derivatives occurring in the partial differential equations in 2 and 3 dimensions and thereafter we will take up few applications in the next lectures.
