

**Introduction to Mechanical Vibration**  
**Prof. Anil Kumar**  
**Department of Mechanical and Industrial Engineering**  
**Indian Institute of Technology – Roorkee**

**Lecture - 02**  
**Addition of two harmonic motions and beat phenomenon**

We will discuss the addition of two harmonic motions and beat phenomenon. As we discuss that, what is simple harmonic motions? When we are going to add the two motions, what are the resultants that we are getting out of these two motions? So, the contents of this lecture will follow the simple harmonic motion, we will recall it and then the phase difference and then we will discuss the addition of two synchronous harmonic motions, means they have the same frequencies.

**(Refer Slide Time: 00:55)**

## CONTENTS

- SIMPLE HARMONIC MOTION
- PHASE DIFFERENCE
- ADDITION OF TWO SYNCHRONOUS HARMONIC MOTIONS
- ADDITION OF TWO NEAR SYNCHRONOUS HARMONIC MOTIONS- BEATS
- BEATS OF TWO MOTIONS OF SAME AMPLITUDE

Of course there will be phase difference in the two motions. Then we will discuss addition of two near synchronous harmonic motions, means the difference between the two frequencies is slight and this will give rise to the phenomena like beats phenomenon. And then we will derive the expressions for these motions.

**(Refer Slide Time: 01:46)**

## SIMPLE HARMONIC MOTION (SHM)

- A periodic motion of a particle whose acceleration is always directed towards the mean position and is proportional to its distance from the mean position
- The motion of the projection of a particle moving round a circle with uniform angular velocity, on a diameter
- Amplitude: the maximum displacement of a vibrating body from the mean position

So here, we recall the simple harmonic motion that simple harmonic motion is the motion, a periodic motion that a particle makes, when the acceleration is proportional to the distance from the mean position and it is directed towards the mean position. And the simple harmonic motion is usually expressed in terms of sinusoidal or cosine motion.

(Refer Slide Time: 02:12)

### PHASE DIFFERENCE BETWEEN TWO VECTORS OR SHMs

Consider two vibratory motions denoted by

$$x_1 = X_1 \sin \omega t$$

$$x_2 = X_2 \sin(\omega t + \phi)$$

The maximum of the second vector would occur  $\phi$  radians earlier than that of the first vector.

Like here, we can see that we have two simple harmonic motions. So  $x_1 = X_1 \sin \omega t$ . Here the small letter is showing the overall function of this motion. And capital X is showing the amplitude of this simple harmonic motion. Then we have the second motion,  $x_2$ , that is  $X_2 \sin(\omega t + \phi)$ . So these two motions have different amplitudes and there is phase difference. So, these motion  $x_2$  is leading with  $\phi$  radian to this  $x_1$ .

So, we can see here. So, this is the vector diagram. So we can, on the vector diagram, we can see, so this is  $x_1$ , so both have the same frequencies, so the both vector this OP1 and OP2, they are moving with the constant angular velocity  $\omega$ . OP1 has this  $\omega t$ , this  $\theta$  and OP2 vector that is the angle  $\omega t + \phi$ . And this is the corresponding simple harmonic motion plotted on the  $\theta$  axis. Now, we want to add these two motions. What is the resultant of these two motions? That, we have to find out.

(Refer Slide Time: 03:53)

$$\begin{aligned}
 x_1 &= X_1 \sin \omega t \\
 x_2 &= X_2 \sin(\omega t + \phi) \\
 x &= x_1 + x_2 = X \sin(\omega t + \beta) \\
 &= X_1 \sin \omega t + X_2 \sin(\omega t + \phi) = X [\sin \omega t \cos \beta + \cos \omega t \sin \beta] \\
 X_1 \sin \omega t + X_2 [\sin \omega t \cos \phi + \cos \omega t \sin \phi] &= X [\sin \omega t \cos \beta + \cos \omega t \sin \beta] \quad \text{--- (a)} \\
 \sin \omega t [X_1 + X_2 \cos \phi] + \cos \omega t \cdot X_2 \sin \phi &= X \cos \beta \sin \omega t + X \sin \beta \cos \omega t \\
 X \cos \beta &= X_1 + X_2 \cos \phi \quad \text{--- (b)} \\
 X \sin \beta &= X_2 \sin \phi \quad \text{--- (c)} \\
 X^2 \cos^2 \beta + X^2 \sin^2 \beta &= (X_1 + X_2 \cos \phi)^2 + (X_2 \sin \phi)^2 \\
 \cos^2 \beta + \sin^2 \beta &= 1 \\
 \Rightarrow X^2 &= (X_1 + X_2 \cos \phi)^2 + (X_2 \sin \phi)^2 \\
 \Rightarrow X &= \sqrt{(X_1 + X_2 \cos \phi)^2 + (X_2 \sin \phi)^2} \quad \checkmark \\
 \frac{\text{Eq. (c)}}{\text{Eq. (b)}} \quad \frac{X \sin \beta}{X \cos \beta} &= \frac{X_2 \sin \phi}{X_1 + X_2 \cos \phi} \\
 \tan \beta &= \frac{X_2 \sin \phi}{X_1 + X_2 \cos \phi} \\
 \beta &= \tan^{-1} \left( \frac{X_2 \sin \phi}{X_1 + X_2 \cos \phi} \right) \quad \checkmark
 \end{aligned}$$

So, these are the two motions and we want to add these two motions. So, let us say that this is the resultant  $x$  that is  $x_1 + x_2$ . And so we can write  $x_1 \sin \omega t + x_2 \sin(\omega t + \phi)$ . Now, these two motions the same frequencies, therefore the resulting motions will also have the same frequency. And therefore let us assume that the resultant motion is also harmonic, so it is  $X \sin(\omega t + \text{some different phase angle } \beta)$

So, now we will solve these equations. Because we have, if you want to know the resultant, we must know  $X$  and we must know  $\beta$ . So we can write this. So,  $X_1 \sin \omega t$ , we can write this like  $X_2$ , so  $\sin(a + b) = \sin a \cos b + \cos a \sin b$ , so we can write  $(\sin \omega t \cos \phi + \cos \omega t \sin \phi)$ . And here also we can open,  $X$ , so  $(\sin \omega t \cos \beta + \cos \omega t \sin \beta)$

Now, we separate out the terms. Let us here we write,  $\sin \omega t$  and here we can write  $(X_1 + X_2 \cos \phi) + \cos \omega t$  into  $X_2 \sin \phi$ . Now, let us say this is equation A. Now we compare from both sides, the co-efficient of  $\sin \omega t$  and  $\cos \omega t$ . So here we can write, here the co-efficient of  $\sin \omega t$  is  $X_1 + X_2 \cos \phi$ , here it is  $X \cos \beta$ . So we can write,  $X \cos \beta = X_1 + X_2 \cos \phi$ .

And similarly, we can write  $X \sin \beta = X_2 \sin \phi$ . So, these are other two equations, let us say B and C. Now, we want to know  $X$  and we want to know  $\beta$ . So, we will do square and under root. So, we do here  $X^2 \cos^2 \beta + X^2 \sin^2 \beta = (X_1 + X_2 \cos \phi)^2 + (X_2 \sin \phi)^2$ . Now  $X^2$ , we know that  $\cos^2 \beta + \sin^2 \beta = 1$ .

So,  $\cos^2 \beta + \sin^2 \beta = 1$ . Therefore, we can write  $X^2 = (X_1 + X_2 \cos \phi)^2 + (X_2 \sin \phi)^2$ . So from here, we can find  $X = \sqrt{(X_1 + X_2 \cos \phi)^2 + (X_2 \sin \phi)^2}$ . So here, we have got the amplitude  $X$ . And these, we know  $X_1$ ,  $X_2$  and we know  $\phi$ , from these two motions. So, we can also find the  $X$ .

Now, we have to know the  $\beta$ . So,  $\beta$  we can know if we divide the equation c by equation b. So, we can find, like  $X \sin \beta \text{ upon } X \cos \beta = X_2 \sin \phi \text{ upon } X_1 + X_2 \cos \phi$ . So, here  $X$  will be cancelled out and we will have  $\tan \beta = X_2 \sin \phi \text{ upon } X_1 + X_2 \cos \phi$ . So, here we can find  $\beta = \tan^{-1} X_2 \sin \phi \text{ upon } X_1 + X_2 \cos \phi$ . So, here we have got  $X$  and we have got  $\beta$ . So, we have got the resultant that is the addition of the two motions.

So, it means that the addition of the two motions is  $X \sin \omega t + \beta$ , where  $X$  is under root  $X_1 + X_2 \cos \phi$  whole square +  $X_2 \sin \phi$  square under root. And  $\beta = \tan^{-1} X_2 \sin \phi \text{ upon } X_1 + X_2 \cos \phi$ . So, the resultant of two synchronous harmonic motions is a harmonic motion with the same frequency. So, here we discussed the addition of the two synchronous harmonic motions.

Now, we will discuss the addition of the two near synchronous harmonic motions means there is slight difference in the frequencies of the two motions.

(Refer Slide Time: 12:26)

### ADDITION OF TWO NEAR SYNCHRONOUS HARMONIC MOTIONS

- When two harmonic motions, with frequencies close to one another, are added, the resulting motion exhibits a phenomenon known as beats

$$x_1 = a \sin \omega_1 t$$

$$x_2 = b \sin \omega_2 t$$

- The resultant motion,  $x = x_1 + x_2 = a \sin \omega_1 t + b \sin \omega_2 t$
- If  $\omega_1$  and  $\omega_2$  are different, then the resulting motion is not sinusoidal.
- When the two frequencies are only slightly different, the phase difference between the rotating vectors keeps on shifting slowly and continuously.
- At a time when they are in phase, the resultant amplitude is the sum of the amplitude of individual motions (a+b), and when they are out of phase, the amplitude is equal to the difference of the individual amplitudes (a-b).

So, when two harmonic motions, with frequencies that are very close to each other, are added they exhibit some phenomenon that is known as beat phenomenon and if there are two motions, so,  $x_1 = a \sin \omega_1 t$  and  $x_2 = b \sin \omega_2 t$ , where a and b are amplitudes of the two motions and  $\omega_1$  and  $\omega_2$  are the frequencies and  $\omega_1$  and  $\omega_2$ , when they are very close, but not the same, then the beats phenomenon occurs.

So, if  $\omega_1$  and  $\omega_2$  are different, then the resulting motion is not sinusoidal. And when they are slightly different, the phase difference vector rotates continuously and keeps shifting. So, at certain instant of time, when they are in phase, the resultant motion is maximum that is amplitude is maximum that is (a+b), sum of (a and b) and when they are out of phase, the amplitude is minimum and that is the difference of the two amplitudes of the two motions.

So, we will now write the equations for the beats phenomenon.

(Refer Slide Time: 14:21)

$x_1 = a \sin \omega_1 t$   
 $x_2 = b \sin \omega_2 t$   
 The resultant motion  
 $x = x_1 + x_2$   
 $= a \sin \omega_1 t + b \sin \omega_2 t$   
 Assume that  $\omega_2 - \omega_1 = \delta$   
 $\omega_2 = \omega_1 + \delta$   
 $x = a \sin \omega_1 t + b \sin (\omega_1 + \delta) t$   
 $= a \sin \omega_1 t + b [\sin \omega_1 t \cos \delta t + \cos \omega_1 t \sin \delta t]$   
 $= (a + b \cos \delta t) \sin \omega_1 t + b \sin \delta t \cos \omega_1 t$   
 Amplitude  $= \sqrt{(a + b \cos \delta t)^2 + (b \sin \delta t)^2}$   
 $= \sqrt{a^2 + b^2 \cos^2 \delta t + 2ab \cos \delta t + b^2 \sin^2 \delta t}$   
 $= \sqrt{a^2 + b^2 + 2ab \cos \delta t}$   
 When  $\cos \delta t = 1$ ,  
 Amplitude  $= \sqrt{a^2 + b^2 + 2ab}$   
 $= \sqrt{(a+b)^2} = (a+b)$   
 When  $\cos \delta t = -1$   
 Amplitude  $= \sqrt{a^2 + b^2 - 2ab}$   
 $= \sqrt{(a-b)^2} = (a-b)$   
 Let's take a special case  
 $a = b = X$   
 Amplitude  $= \sqrt{X^2 + X^2 + 2XX \cos \delta t}$   
 $= \sqrt{2X^2 + 2X^2 \cos \delta t}$   
 $= \sqrt{2X^2 [1 + \cos \delta t]}$   
 $= \sqrt{2X^2 [1 + 2 \cos^2 \frac{\delta t}{2} - 1]}$   
 $= \sqrt{4X^2 \cos^2 \frac{\delta t}{2}}$   
 $= \pm 2X \cos \frac{\delta t}{2}$

So, we have two motions  $x_1 = a \sin \omega_1 t$  and  $x_2 = b \sin \omega_2 t$ . The resultant motion you want to get  $x = x_1 + x_2$ . That is equal to  $a \sin \omega_1 t + b \sin \omega_2 t$ . Now here, we have assumed that  $\omega_2 - \omega_1 = \delta$ , a very small quantity, so here we can write  $\omega_2 = \omega_1 + \delta$ . Then we write  $x = a \sin \omega_1 t + b \sin (\omega_1 + \delta) t$ .  $= a \sin \omega_1 t + b$ , here  $\sin a + b$ , so we will open it, so  $(\sin a, \text{so } \omega_1 t \cos \delta t + \cos \omega_1 t \sin \delta t)$ . So we can separate out the terms of  $\sin \omega_1 t$ .

So, we can write  $(a + b \cos \delta t) \sin \omega_1 t + b \sin \delta t \cos \omega_1 t$  into  $\cos \omega_1 t$ . So now we want to know the amplitude. And amplitude will be  $=$  this square plus this square under root. So here,  $b^2 \cos^2 \delta t$  and here is  $b^2 \sin^2 \delta t$ . So, we can write  $b^2 (\cos^2 \delta t + \sin^2 \delta t)$  and  $\cos^2 \delta t + \sin^2 \delta t = 1$ . So it will be  $b^2$ . So it is like  $a^2 + b^2 + 2ab \cos \delta t$ .

Now when  $\cos \delta t = 1$ . Because this is  $\cos \delta t$ , where is  $\cos \delta t$ , where is between  $-1$  and  $1$ , it where is between minus one and one. So when  $\cos \delta t = 1$ , the amplitude  $=$  root  $a^2 + b^2 + 2ab$ . And so it is  $(a + b)$  whole square under root. So, it is equal to  $(a+b)$ . When  $\cos \delta t = -1$ , amplitude  $=$  root  $a^2 + b^2 - 2ab$ , because  $\cos \delta t = -1$ , so it is  $-2ab$ .

So we can write under root  $(a - b)$  whole square, because  $(a - b)$  whole square is  $a^2 + b^2 - 2ab$ . So it is  $(a - b)$ . So therefore, when we have the two motions,  $x_1 = a \sin \omega_1 t$  and  $x_2 = b \sin \omega_2 t$ , the resultant motion will have the maximum amplitude  $(a + b)$ . So resultant amplitude continuously keeps on changing from maximum that is  $(a + b)$  to minimum that is  $(a - b)$  with a frequency that is equal to the difference between the individual component frequencies.

So, this phenomenon is known as beats. Now, let us take a special case, so let us take a special case, when  $a = b = X$ . So, we assume that the amplitude of the two motions is same. So, let us write this expression, so here, we will have amplitude = under root  $a^2 + b^2 + 2ab \cos \Delta t$ , now we put  $a = b = X$ , so it will be  $X^2 + X^2 + 2X^2 \cos \Delta t$ , so it is equal to  $2X^2 + 2X^2 \cos \Delta t$ , so = under root  $2X^2 (1 + \cos \Delta t)$ .

So we can write, equal to under root  $2X^2 (1 + \cos 2\theta) = 2X^2 \cos^2 \theta$ , so here we write  $\cos^2 \theta$ . So we will use this, this formula to open to break this term, so  $(1 + \cos 2\theta)$ . Here  $2\theta$  is  $\Delta t$ , so  $\theta$  is  $\Delta t$  by two. So here, we can write  $\Delta t$  by two. So, this one and one will cancel out. And we will get  $4X^2 \cos^2 \Delta t$  by 2.

So here we can have, this equal to  $\pm 2X \cos \Delta t$  by 2. So here, we see that the amplitude varies, as the function of  $\cos \Delta t$  by 2. And we can see these from, clearly from these diagram.

**(Refer Slide Time: 24:56)**

## BEATS OF TWO MOTIONS OF SAME AMPLITUDE

- Assume two motions having same amplitude:  $x_1 = X \sin \omega_1 t$ ,  $x_2 = X \sin \omega_2 t$
- Beat Frequency,  $\delta = \omega_2 - \omega_1$ , Maximum amplitude =  $2X$ , Minimum amplitude =  $0$ .

So here, this is the resultant wave that is moving. However, the amplitude is moving in a  $\cos \delta t$  minus, because it is a function of  $\cos \delta t$  by two, so this is a cosine, so here it is maxima and this way it is moving and then the next maxima is coming here. In between these, we can see that there is the beat. So, beat can be considered as the time period between these two nodes, or two maximers.

So, therefore the beat frequency, beat time period is half the time period of the cosine curve or the beat frequency is twice the frequency of the cosine curve that is two times  $\delta$  by two that is equal to  $\delta$  and  $\delta$  is, we assumed  $\omega_2$  minus  $\omega_1$  that is the difference between the two frequencies. So here, when we have same amplitude, so we see that the maximum is  $2X$  then minus  $2X$  and here this minimum is zero here.

And so, the amplitudes build up, so amplitude is builds up, so here it is building and then diminishes in a regular pattern. So therefore, we whenever the two motions, two harmonic motions, with these close frequencies are there, they will show the beats phenomenon, where the amplitude will build up and then it will diminish in a regular pattern. So we would stop this lecture and we will meet again. Thank you for your attention.
