Lecture - 24
Input Modeling: Multivariate Input Models

Welcome to the lecture on Multivariate Input Models. So, in this lecture we will talk about the joint distribution functions then the covariance correlation among the random variables. So, as we know that in the simulation many a times we have to deal with more number of random variables.

(Refer Slide Time: 00:48)

Joint probability distribution function

- In simulation, one may deal with n random variables.
- For two random variables X and Y
 - $p(x,y) = P(X=x, Y=y)$ for all x,y
 - $p(x,y)$ is called joint probability mass function of X and Y
- X and Y are independent, if
 - $p(x,y) = p_X(x)p_Y(y)$ for all x,y
 - $p_X(x)$ and $p_Y(y)$ are called marginal probability mass function of X and Y .

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So, in that case where you have 2 random variables: that is when n equal to 2 in those cases $p_{x,y}$ means the probability of x you have X and Y as random variable. So, if the X equal to small x and capital Y , equal to small y . So, if that is. So, that is basically known as the joint probability mass function of x and y . So, if $p_{x,y}$ is equal to p_X into p_Y , then they are said to be independent and if they are not so if the $p_{x,y}$ is not equal to p_X into p_Y in that case they are said to be dependent. And $p_{X,X}$ and $p_{X,Y} p_{Y,Y}$ they are called the marginal probability mass function of x and y .

So, this random variables may be either discrete or it may be you know continuous and we must know how to see whether the 2 random variables which have been defined

whether they are independent or not. So, for that certainly if the $p_{x,y}$ will be $p_x \times p_y$ then you can say that they are independent otherwise they are dependent.

Now, before that before we go to that now even this works well even for the continuous distribution functions. Now the so we must know certain definitions for that as we know that.

(Refer Slide Time: 02:32)

The image shows handwritten mathematical derivations on a whiteboard, divided into two columns. The left column deals with discrete random variables, and the right column deals with continuous random variables.

Left Column (Discrete):

- Formulas for marginal probabilities: $p_X(x) = \sum_{\text{all } y} p(x,y)$ and $p_Y(y) = \sum_{\text{all } x} p(x,y)$.
- Definition of independence: $p(x,y) = p_X(x)p_Y(y)$ if X and Y are independent.
- Example: X and Y as two discrete random variables with $p(x,y) = \begin{cases} \frac{x}{27} & \text{for } x=1,2 \text{ and } y=2,3,4 \\ 0 & \text{otherwise} \end{cases}$.
- Calculation of $p_X(x)$: $p_X(x) = \sum_{y=2}^4 \frac{x}{27} = \frac{3x}{27} = \frac{x}{9}$ for $x=1,2$.
- Calculation of $p_Y(y)$: $p_Y(y) = \sum_{x=1}^2 \frac{x}{27} = \frac{3}{27} = \frac{1}{9}$ for $y=2,3,4$.
- Conclusion: $p_X(x)p_Y(y) = \frac{x}{9} \cdot \frac{1}{9} = \frac{x}{81} \neq \frac{x}{27} = p(x,y)$, so X and Y are dependent.

Right Column (Continuous):

- Joint PDF: $f(x,y) = 32x^3y^7, 0 \leq x \leq 1, 0 \leq y \leq 1$.
- Marginal PDFs: $f_X(x) = \int_0^1 f(x,y) dy = \int_0^1 32x^3y^7 dy = 32x^3 \left[\frac{y^8}{8} \right]_0^1 = 4x^3$ and $f_Y(y) = \int_0^1 f(x,y) dx = \int_0^1 32x^3y^7 dx = 32y^7 \left[\frac{x^4}{4} \right]_0^1 = 8y^7$.
- Product of marginals: $f_X(x)f_Y(y) = 4x^3 \cdot 8y^7 = 32x^3y^7 = f(x,y)$.
- Conclusion: X and Y are independent.

So, in that case $p_{x,x}$ is nothing but for all y this is $p_{x,y}$, similarly $p_{y,y}$ is for all x $p_{x,y}$. So, this way you find the $p_{x,x}$ and $p_{y,y}$ and if $p_{x,y}$ is equal to $p_{x,x}$ multiplied by $p_{y,y}$ then we say that x and y are independent. Now in the case of continuous random variables this sign will be you know replaced with the integral sign and in that case $d x$ and $d y$ will come whatever the random variable we choose. So, for example, we can have certain examples suppose we have an example the which is given like suppose we have X and Y as 2 discrete random variables. So, they are defined like this $p_{x,y}$ they are defined as x into y by 27 and for x equal to 1 and 2 and y equal to 2 3 and 4 and this is 0 otherwise.

Now, we have to see whether these 2 random variables x and y they are independent or they are dependent. So, for that as we know if the $p_{x,y}$ so for that as we know if $p_{x,y}$ is equal to p_x of x and p_y of y then in that case x and y are said to be independent. So, this is the condition and it is already defined what is $p_{x,x}$ and what is $p_{y,y}$. So, let us find the $p_{x,x}$. So, $p_{x,x}$ will be all the summation of all the values. So, you have $p_{x,y}$.

So, that is $x y$ by 27 over all y . So, y is from 2 to 4. So, y varying from 2 to 4 so, for all the values these are discrete values. So, we are taking every value you know y equal to 2 y equal to 3 and y equal to 4. So, if you do that. So, in that case what we see. So, y will be varying. So, it will be once $2 x$ by 27, plus $3 x$ by 27, plus $4 x$ by 27. So, that is $9 x$ by 27. So, it will be x by 3. So, we have x value as 1 and 2. So, we get $p x x$ equal to x by 3, similarly we can get $p y y$ $p y y$ will be again summation of all x . So, x is varying basically from 1 and 2. So, that is x equal to 1 to 2 and in that case you have $x y$ by 27. So, it will be once we take 1 so y by 27 plus 2 y by 27 so 3 y by 27 that is y by 9.

Now, what we see is if we multiply now what we get whether we are getting $p x y$ equal to $p x x$ into $p y y$ or not. So, if we multiply these 2 $p x x$ into $p y y$ it will be we have got $p x x$ as x by 3 and this as y by 9. So, it is $x y$ by 27 and it is nothing but it is equal to $p x y$. So, it means x and y can be said to be independent. So, x and y are independent.

So, this is how for a discrete random variable for the joint probability distribution function we can say and we can find whether they are dependent or not. Let us check it check 1 for, we can also check this you know this type of independence or dependence, for even the continuous distribution function and that we can do once we solve the problems in the next lectures or so.

(Refer Slide Time: 07:50)

Dependence between two random variables

- The covariance between the random variables X and Y , denoted by $\text{Cov}(X, Y)$, is defined by

$$\begin{aligned}\text{Cov}(X, Y) &= E\{[X - E(X)][Y - E(Y)]\} \\ &= E(XY) - E(X)E(Y)\end{aligned}$$
- The covariance is a measure of the dependence between X and Y . $\text{Cov}(X, X) = \text{Var}(X)$.

IF ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 3

Now, further we must know that, what is the dependence between 2 random variables? So, how the dependence is to be calculated? So, let us see how we do it for a continuous

random variable. Now let us take another example where x and y are continuous random variables and the $f_{x,y}$ is defined as $32x^3y^7$. So, in that the range for x is 0 to 1 and y is again 0 to 1. Now in this case again because here we see that the x and y is defined in intervals. So, x and y are basically the continuous random variables, now in this case again we have to see we have to check whether the x and y are independent or not. So, we will find $f_{x,x}$ and this will be integral of $f_{x,y} dy$ for all y . So y is between 0 to 1.

So, it will be $32x^3y^7$ integral dy 0 to 1. So, it will be $32x^3$ into $y^7 dy$ will be y^8 by 8. So, it will be $4x^3y^8$ and the y value is changing from 0 to 1. So, it will be $4x^3$ and the next time it will be 0. So, it will be $4x^3$, then $f_{y,y}$ this will be again it will be $f_{x,y}$ this time for all x . So, it will be dx and x is also varying from 0 to 1. So, this will be coming as integral 0 to 1 $32x^3y^7 dx$. So, it will be $32y^7$ into x^4 by 4 and this will be between 0 and 1. So, it will be 8 into y^7 . So, what we see that we get $f_{x,x}$ and $f_{y,y}$, now if we multiply them $f_{x,x} f_{y,y}$ it will be equal to $4x^3$ multiplied by $8y^7$. So, it is $32x^3y^7$ what we see is that in this way we see that this is nothing but same as $f_{x,y}$.

So, since $f_{x,y}$ is same as $f_{x,x}$ into $f_{y,y}$ it means x and y are independent. So, this is how you check if the random variable either discrete or continuous their dependence or independence can be checked. Now we have to see the dependence between the 2 random variables so the dependence between 2 random variables for that basically there are certain parameters which are computed, and we compute the covariance and covariance between 2 random variables is defined as $Cov(X,Y)$ we write it as and it will be $E(XY)$ minus $E(X)$ into $E(Y)$.

So, as we know that we have the joint probability distribution function or probability mass function. So, we have the $E(XY)$ we have to compute $E(XY)$ and then we have to compute $E(X)$ and both $E(Y)$ and then we have to get the difference of that. So, this way you get the covariance. So, covariance is basically a measure of dependence between X and Y . So, if we try to see what is covariance X,X . So, if Y is taken as X it is coming same as the variance of X . So, variance X we find as $E(X^2)$ minus n times $E(X)$ or $E(X)^2$. So, this way we get the variance X . So, that is what we get when we get covariance X,X .

Now, what do you mean by covariance $X Y$. So, when the covariance $X Y$ is 0 it means the X and Y are uncorrelated.

(Refer Slide Time: 13:16)

$\text{Cov}(X, Y) = 0$ means X and Y are *uncorrelated*
 > 0 means *positively correlated*
 < 0 means *negatively correlated*

- Independent random variables are uncorrelated.
- The *correlation* between the random variables X and Y , denoted by $\text{Cor}(X, Y)$, is defined by

$$\text{Cor}(X, Y) = \frac{\text{Cov}(X, Y)}{\sqrt{\text{Var}(X)\text{Var}(Y)}} \quad -1 \leq \text{Cor}(X, Y) \leq 1$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

And if it is 0 I mean it is more than 0 it means they are positively correlated and if it is less than 0 means it is negatively correlated. Basically covariance is nothing but you have $X_1 - \mu_1$ into $X_2 - \mu_2$. So, if it is more than 0 means if X_1 is more than μ_1 , in that case X_2 will also be more than μ_2 . So, that is known as positively correlated if X_1 value is larger than the mean values than for another random variable also its values will be larger than the mean values.

So, that is what in the meaning of positively correlated. Similarly if it is negatively correlated means the value is less than 0 in those cases the X_1 of the random variable has values, less than the mean in that case for the other random variable its value will be more than its mean. So, in those cases what will happen that their product will be negative? So, that is why if it is less than or more than 0 it has certain significance, whenever we have independent random variables they are said to be uncorrelated. So, normally you have the random independent random variables these are uncorrelated.

Now, for the correlation there is another parameter which is defined that is ρ and that is correlation $X Y$. So, this is nothing but covariance $X Y$ by under root variance X into variance Y . So, this is how you find the correlation and this correlation will be varying

from minus 1 to plus 1. So, if it is closed to minus 1 it is highly negatively correlated and if it is closed to plus 1 it is highly positively correlated the 2 random variables and if it is near to 0 it means they are uncorrelated they are independent random numbers.

So, this is how you find the different you know correlation parameters by which you calculate and you come to the conclusion whether it is dependent or not dependent. Let us see how you compute the correlation and you come to this conclusion whether the variable is independent or not.

(Refer Slide Time: 16:10)

Multivariate Input models

- If X_1 and X_2 are normally distributed, then dependence between them can be modeled by the bivariate normal distribution with parameters $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$ and $\rho = \text{Corr}(X, Y)$.
- For n independent and identically distributed pairs, $(X_{11}, X_{21}), (X_{12}, X_{22}), \dots, (X_{1n}, X_{2n})$, the sample covariance is

$$\widehat{\text{cov}}(X_1, X_2) = \frac{1}{n-1} \sum_{j=1}^n (X_{1j} - \bar{X}_1)(X_{2j} - \bar{X}_2)$$

$$= \frac{1}{n-1} \left(\sum_{j=1}^n X_{1j} X_{2j} - n \bar{X}_1 \bar{X}_2 \right)$$

$$\hat{\rho} = \frac{\widehat{\text{cov}}(X_1, X_2)}{\hat{\sigma}_1 \hat{\sigma}_2}$$

III ROORKEE NPTEL ONLINE CERTIFICATION COURSE 5

So, before that before we go to further see with the problem where we try to find the correlation let us see that further if you have X_1 and X_2 as the normally distributed 2 random variables. So, their dependence can be modelled by the variate, bi-variate normal distribution.

So, as we know that once you have the data's. So, in the normal distribution case you have the parameters like μ and σ that is μ is mean σ is the standard deviation. So, σ^2 will be your variance. So, in those cases you will have $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$ and then you have to find the correlation X_1, X_2 . So, correlation X_1, X_2 as we discussed, it will be ρ and if you have n independent and identically distributed pairs like $X_{11}, X_{21}, X_{12}, X_{22}, X_{1n}$ and X_{2n} all that. So, in those cases how you find the sample covariance that is given by this formula. So, as we see you have the covariance of x_1 and x_2 . So, we are finding this by x_{1j} minus this is

$\bar{x}_1$. So, this $\bar{x}_1$. So, you have 2 random variables given and they are going like this. So, you have x_{1j} and this is $j = 1, 2, \dots, n$. So, $x_{1j} - \bar{x}_1$. So, that is your μ_1 similarly $x_{2j} - \bar{x}_2$ and then it will be divided by $n - 1$. So, this will be basically covariance. So, it will be nothing but $\frac{1}{n-1} \sum_{j=1}^n (x_{1j} - \bar{x}_1)(x_{2j} - \bar{x}_2)$.

So, this is how you are basically finding the covariance and once you find the covariance the covariance value will be divided with this estimated value of so this is unbiased estimator of standard deviation 1 and 2. So, we had seen in the earlier formula this was here it was under root variance 1 and variance 2. So, this is $\sigma_1 \sigma_2$. So, this is how you compute the correlation now let us see how we solve if we face certain problems of that type.

(Refer Slide Time: 18:57)

Q. X_1 - average lead time to deliver (in months)
 X_2 - annual demand

Lead time	6.5	4.3	6.9	6.0	6.9	6.9	5.8	7.3	4.5	6.3
Demand	103	83	116	97	112	104	106	109	92	96

$\bar{X}_1 = \frac{61.4}{10} = 6.14, \bar{X}_2 = 101.8$
 $\hat{\sigma}_1 = 1.02, \hat{\sigma}_2 = 9.93$
 $\sum_{j=1}^{10} X_{1j} X_{2j} = 6328.5$

$Cov(X_1, X_2) = \frac{1}{9} [6328.5 - 10(6.14)(101.8)]$
 $= 8.66$
 $Corr(X_1, X_2) = \frac{Cov(X_1, X_2)}{\hat{\sigma}_1 \hat{\sigma}_2} = \frac{8.66}{1.02 \times 9.93} = 0.86$

$(X_1 - \mu_1)(X_2 - \mu_2)$
 $\hat{\rho} \sim (+ve)$
 $X_1 > \mu_1, X_2 > \mu_2$

Now, suppose a problem is there like this that you have x_1 which is average lead time to deliver and x_2 is the annual demand. So, you have x_2 as annual demand and x_1 is average lead time to deliver in months. So, these are 2 random variables which have you have the data and this is lead time and demand values are given. So, for the, first value is 6.5 and this is 103, then you have 4.3 83 further you have 6.9 116 you have 6 and 97, you have 6.9 112 then further 6.9 and this is 104. So, you have further 5.8 and this is 106. So, for the last 10 years you have 10 data further you have 7.3 and this is 109, then you have 4.5 and 92 and then you have 6.3 and 96. So, these are the data which you have

for the 2 random variables 1 is talking about the lead time another is talking about the annual demand.

Now, in this case you have to find whether there is any correlation between them for correlation you need to calculate covariance for covariance you need to calculate summation $\sum x_1 j \times x_2 j$ and then you need to compute the mean sample means for the 2 random variables and also you need to calculate the variance for them. So, that you get the standard deviation and further you can get the value of covariance.

So, let us if we do the analysis over this what we get is. So, $\bar{x}_1$ for that we have to add these values and these values once added it has to be divided by 10. So, this value comes, but to be 61.4 and then you divide it by 10. So, it will be 6.14 then similarly you have to find $\bar{x}_2$ mean value of x_2 . So, x_2 also again we are going to add these 10 values and divide it by 10. So, this is coming out to be 101.8. Now we need to compute the sigma 1 and sigma 2.

So, sigma 1 is calculated as. So, this is estimator value basically. So, this is computed to be 0.021.02, similarly you compute the sigma 2 value that is estimated value of sigma 2. So, that comes out to be 9.93 this can be computed using the standard formulas for that you need to have these square and then further we do the necessary computation. So, you can get this sigma 1 sigma 2 $\bar{x}_1$ and $\bar{x}_2$ and ever thing what you need is summation $\sum x_1 j \times x_2 j$.

So, summation of $\sum x_1 j \times x_2 j$ and as we know j is varying from 1 to 10. So, what we will do we have do the multiplication of this and this plus this and this plus this and this plus this and this like that you have to multiply and then we have to add it. So, j equal to 1 to 10 this summation this summation will come out to be 63 28.5. So, this is nothing but the summation suppose here 103 into 6.5 plus 83 into 4.3, plus 106 into 6.9, plus 97 into 6, plus 112 into 6.9, plus 104 into 6.9, plus 106 into 5.8, plus 109 into 7.3, plus 92 into 4.5, plus 96 into 6.3. So, this will come out to be 632 8.5 that is $\sum x_1 j \times x_2 j$ not formula is shown here. So, this value is coming out to be 63 28.5.

Now we have all the values, we have this value known, we have n as 10 $\bar{x}_1$ we know $\bar{x}_1$ is known to be 6.1 4 $\bar{x}_2$ we know. So, and we know also n is 10. So, we have to get the covariance. So, covariance we will be finding covariance will be actually it will be $1 \text{ by } n \text{ minus } 1$ so $1 \text{ by } 9$ and then summation of $\sum x_1 j \times x_2 j$. So, that is 63 28.5

and further minus n times $\bar{x}_1 \times \bar{x}_2$. So, n is 10 10 times $\bar{x}_1$ bar and $\bar{x}_2$ bar $\times \bar{x}_1$ bar is 6.1 4 and $\bar{x}_2$ bar is 101.8.

So, this is coming out we have to do this computation and this will come out to be 8.66. So, this is coming out to be 8.66, now we have to find the correlation how they are correlated. So, for finding the correlation you have to divide this covariance $x y$ with σ_1 estimator σ_2 estimator. So, σ_1 estimator and σ_2 estimator we know. So, correlation $x y$ that is estimator ρ this will be covariance $x y$ divided by σ_1 estimator σ_2 estimator.

So, it will be 8.66 divided by $\bar{x}_1$ bar is 6.14. So, this is σ_1 bar is 1.02 and then it will be 9.93. So, this is coming out to be 0.86 now what we see is in this case the ρ value the correlation coefficient value this value is coming out to be 0.86 which is very much close to 1. It means they are very strongly correlated, it means that whenever x is more than μ in that case the x_1 is more than μ x_2 is also more than it is mean by you can look at here by that. Now in this case if you see the x_1 mean mean x_1 is 6.14 now you see and the x_2 mean is 101.8. So, whenever it is more than that 6.5 in that case it is more than it is mean. So, these both are higher.

This is in this case if you look at this value is less than it is mean it is mean is 6.14 and this value is less than it is mean. So, so basically when you have x_1 minus μ_1 and you have x_2 minus μ_2 . So, if the ρ value is positive is nearly plus 1 in those case if x_1 is more than μ_1 then x_2 will also be more than μ_2 in that case only it will be positive and in those cases. So, it will be positive. So, you can see that it is positive when x_1 is more than μ_1 in that case x_2 will also be more than μ_2 .

So, what we see whenever x_1 is more than μ_1 the x_2 is also more than μ_2 it is mean demand mean and lead time mean. So, these values if you look at this is the lead time mean here it is 6.9 it is more than it is mean at the same time it is also more than it is mean 101.8. So, in most of the cases we see that in most of the cases we may not see in every case, but in most of the cases we see by looking at this statistics also it becomes clear, but then statistically if you find you will see that how they are correlated, if it becomes 0 it means that data is quite random they are independent data, that is what you mean to have it and whenever it will be negatively correlated in those cases if 1 value is larger than it is mean in that case it is value will be smaller than it is mean.

So, in that case if you find the correlation it will be coming in an in the negative direction it will be having the value towards less than 0 certainly the correlation coefficient value will be in between 0 and 1, but it will be closed to minus 0.5.6 or minus 0.7 So, in those cases we say that it is negatively correlated and whenever it comes 0. So, basically what we need to study later on that we will have to compare these values.

Now the thing is that we have already studied the significance of that and we have seen in the earlier lecture that what is the significance of this rho and we plotted these diagrams. And we have seen that by looking at the curve you can say that this rho value how it is (Refer Time: 30:23) closed to 0 then we say that that data is independent.

Thank you very much.
