Lecture – 10
Numerical Problems

So, welcome to lecture on mathematical modeling. In this lecture, we will discuss few numerical problems. So, in which we will use the impedance method to write the differential equations, write the equations in complex frequency domain or to obtain the transfer function. So, so far, we have written the differential equation, and then we have taken the Laplace transform, and we obtain the transfer function. We do not need to write the differential equation using the impedance method. We can directly write the transfer functions.

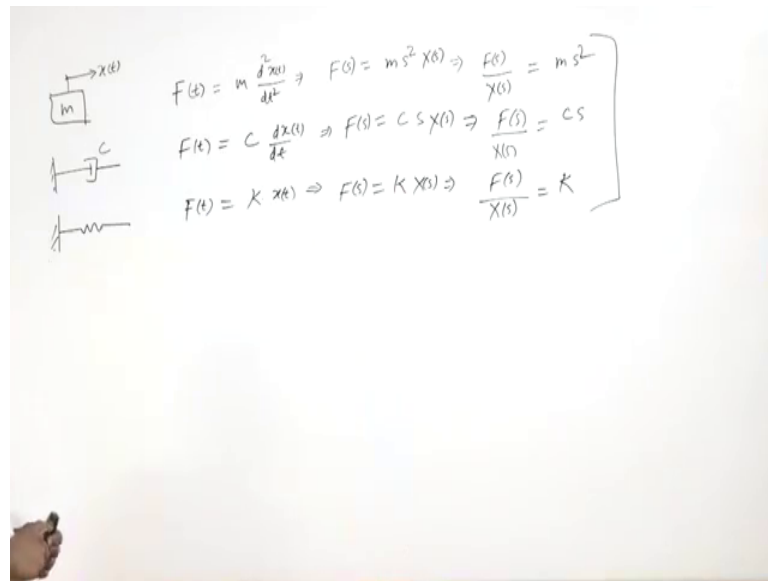

So, we will understand this with the help of few examples. So, first example we will take for a mechanical translational system.

(Refer Slide Time: 01:25)

So, we know that in mechanical translational system we have 3 components. One is mass, then there is damper, and then there is a spring.

(Refer Slide Time: 01:31)

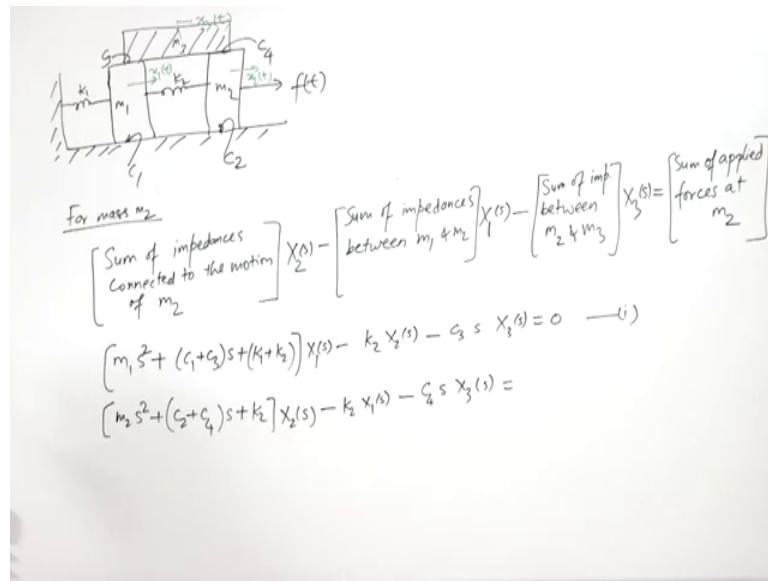

So, here we have we know that for a mass there is force $F t$ equal to m into d square, if this is $x t x t$ by $d t$ square.

So, we take Laplace transform $F s$ equal to $m s$ square into $X s$ with initial conditions 0. So, the impedance is defined as $F s$ by $X s$ that is equal to $m s$ square. Similarly, for a damper the force damper force is $C d x$ by $d t$. And when we take Laplace transform it is $C s X s$. So, impedance is fs by $X s$ and that is equal to $C S$. For a spring force is k into $x t$. We take the Laplace transform. We will find $F s$ equal to k into $X s$.

So, here the impedance is $F s$ by $X s$, that is k . So, these are the impedances of the mechanical elements mass damper and spring. So now, we take the example. So, we take this first example first problem, write the equations of motion in s domain. So, we want to write for this system the equations of motion in complex frequency domain. Once we are able to write the equations in complex frequency domain, we can obtain the transfer function of that system.

So, here we are going to directly write the equations. If you can the impedance method. So, this system is something like this.

(Refer Slide Time: 04:19)

So, here we have a spring, and there is a mass, then there is another a spring, there is another mass. And on these there is one more mass. So, here is another mass, and these are 2 masses. This is \$m_1\$ \$m_2\$, this is \$k_1\$ \$k_2\$. This is \$m_3\$. The damping between. So, these surface it is \$c_1\$ and damping here is \$c_2\$. Here is \$c_3\$ between these 2 blocks there is damping \$c_3\$ and here is \$c_4\$.

So, we apply a force \$f(t)\$ here. Now we assume that this system most and \$x_1(t)\$ \$x_2(t)\$ and \$x_3(t)\$. So now, we have to write the equations of motion for this system using impedance method. So, we can have for mass \$m_1\$. So, sum of impedances connected to the motion of \$m_1\$ into \$x_1(s)\$ minus sum of impedances between \$m_1\$ and \$m_2\$ into \$x_2(s)\$ minus some of impedances between \$m_1\$ and \$m_3\$ into \$x_3(s)\$ equal to sum of applied forces at \$m_1\$.

So now some of impedance is corrected to the motion of \$m_1\$. So, this is \$m_1\$ and the \$m_1\$ is getting impedance due to this a spring this damper \$c_1\$. So, \$c_1\$ is equivalent viscous damping that is coming friction from this surface. And so, we can write it. So, this mass impedance \$m_1 s^2\$, because your mass has the impedance \$m s^2\$. Here we have \$c_1\$ and \$c_2\$ into \$s\$ \$k_1\$ and \$k_2\$. This is the step impedance due to these 2 springs in to \$x_1(s)\$ minus sum of impedances between \$m_1\$ and \$m_2\$. So, between \$m_1\$ and \$m_2\$ there is impedance only due to spring \$k_2\$, that is connecting these 2 masses.

So, minus \$k_2\$ into \$x_2(s)\$. Minus sum of impedance between \$m_1\$ and \$m_3\$. So, between \$m_1\$ and \$m_3\$ there is \$c_3\$. So, minus \$c_3 s\$ into \$x_3(s)\$ equal to sum of applied forces at \$x\$ \$m_1\$.

So, m_1 is not subjected to any force. So, this is 0. So, this is equation number 1. Similarly, for per mass m_2 we can write here m_2 . And then sum of impedance is connected to the motion of m_2 into x_2 s minus sum of impedances between m_1 and m_2 into x_1 s minus sum of impedances between m_2 and m_3 into x_3 s equal to sum of applied forces at m_2 .

So, if we apply these for this mass. So, some of impedance is connected to the motion of m_2 . So, here is k_2 c_2 and c_4 . And the impedance of this mass m_2 s square. So, this is m_2 s square plus c_2 plus c_4 s plus k_2 . And x_2 s x 2 s, minus sum of impedance between m_1 and m_2 is k_2 . So, k_2 into x_1 s minus sum of impedance between m_2 and m_3 so, m_2 and m_3 c_4 . So, it is c_4 s x 3 s that is equal to sum of applied forces at m_2 .

So, here m_2 is subjected to a force F t, and here we have to take the Laplace transform of F t. So, we write F s this is equation number 2. Similarly, for mass m_3 ; so, here motion of m_3 into x_3 .

(Refer Slide Time: 12:44)

The diagram shows three masses m_1 , m_2 , and m_3 on a horizontal surface. m_1 is connected to a fixed wall on the left by a spring k_1 and a damper c_1 . m_1 and m_2 are connected by a spring k_2 and a damper c_2 . m_2 and m_3 are connected by a damper c_4 . m_3 is connected to a fixed wall on the right by a damper c_3 . An external force $f(t)$ is applied to m_2 to the right. Displacements x_1 , x_2 , and x_3 are measured to the right from their respective equilibrium positions.

$$\begin{aligned}
 a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\
 a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 \Rightarrow \Delta = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \\
 a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3
 \end{aligned}$$

For mass m_3

$$\left[\begin{array}{c} \text{Sum of impedances} \\ \text{connected to the motion} \\ \text{of } m_3 \end{array} \right] X_3(s) - \left[\begin{array}{c} \text{Sum of impedances} \\ \text{between } m_1 \text{ \& } m_3 \end{array} \right] X_1(s) - \left[\begin{array}{c} \text{Sum of imp} \\ \text{between} \\ m_2 \text{ \& } m_3 \end{array} \right] X_2(s) = \left[\begin{array}{c} \text{Sum of applied} \\ \text{forces at} \\ m_3 \end{array} \right]$$

$$\begin{aligned}
 (m_3 s^2 + (c_3 + c_4)s) X_3(s) - k_2 X_2(s) - c_3 X_1(s) &= 0 \quad \text{--- (i)} \\
 (m_2 s^2 + (c_2 + c_4)s + k_2) X_2(s) - k_2 X_1(s) - c_4 X_3(s) &= F(s) \quad \text{--- (ii)} \\
 (m_3 s^2 + (c_3 + c_4)s) X_3(s) - c_3 X_1(s) - c_4 X_2(s) &= 0 \quad \text{--- (iii)}
 \end{aligned}$$

Minus sum of impedances between m_1 and m_3 into x_1 s. Minus sum of impedances between m_2 and m_3 and x_2 s and some of applied forces at m_3 . So, your sample sum of impedances connected to the motion of m_3 . So, they are the m_3 s square plus c_3 plus c_4 s x 3 s minus some of impedance between x_1 and between m_1 and m_3 . So, between m_2 and m_3 c_4 s into x_2 s minus here between m_2 and m_3 c_4 s into x_2 s. And that is equal to there is no any force applied here.

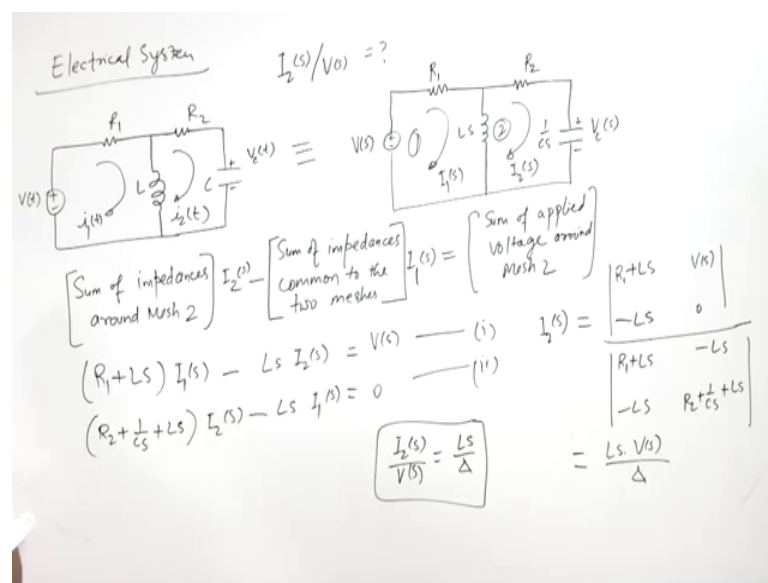

So, it is equal to 0. This is equation number 3. So, we can see that using the impedance method we are able to write the equation of motion in s domain, complex frequency domain directly, and very easily and these 3 equations are like this form. So, a 1 1 x 1 plus a 1 2 x 2 plus a 1 3 x 3 equal to b 1. And this is a 2 1 x 1 plus a 2 2 x 2 plus a 2 3 x 3 equal to b 2. And here a 3 1 x 1 plus a 3 2 x 2 plus a 3 3 x 3 equal to b 3.

So, these equations, because here x 1 x 2 and x 3 or these 3 variables. And these terms are b 1 b 2 b 3 so, 0 F s n 0. Now we can form a matrix delta of a 1 1, a 1 2, a 1 3, a 2 1, a 2 2, a 2 3, a 3 1, a 3 2, a 3 3, this is delta. So, we can use the cramer's rule to find the transfer function. Whether we are interested to find transfer function; that is, x 3 s upon F s or x 2 s upon F s or x 1 s upon F s. So, we can find this transfer function.

So, for example, if we want to find here this x 1; so, x 1 equal to this first column we have to replace with the b 1, b 2, b 3. B 1, b 2, b 3, and these terms will be as such a 1 2, a 2 2, and a 3 2. A 1 2, a 2 3, a 3 3 on delta. So, we can find here x 1 equal to this determinant upon this determinant, and we will get the; so, we can get x 1 s and here is b 1, b 2, b 3. So, there will be F s also coming from this. And so, we can find x 1 s by F s.

So, the transfer functions. So, although these transfer functions, we can find using these 3 equations. Now we take another example that is based on some electrical circuit. So, we have another problem based on electrical circuit.

(Refer Slide Time: 18:20)

So, we have this example. So, we can see here this example. We have this voltage source.

(Refer Slide Time: 19:18)

NUMERICAL PROBLEM

- Find the transfer function $I_2(s)/V(s)$ of the system shown

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

Resistance R_1 , R_2 , inductor L and capacitor C . And there are each current $I_1(t)$ in this loop first loop. And $I_2(t)$ in the second loop and here is the output voltage we are reading at the capacitor that is $v_C(t)$.

So, we have to find the transfer function $I_2(s)$ by $V(s)$. So, $I_2(s)$ by $V(s)$ we have to find. This is the transfer function we have to find. So, we already know that the for an electrical system.

(Refer Slide Time: 20:00)

IMPEDANCES OF AN ELECTRICAL SYSTEM

Component	Voltage-Current	Current-voltage	Voltage-charge	Impedance $Z(s) = V(s)/I(s)$
Capacitor	$v(t) = \frac{1}{C} \int_0^t i(\tau) d\tau$	$i(t) = C \frac{dv(t)}{dt}$	$v(t) = \frac{1}{C} q(t)$	$\frac{1}{Cs}$
Resistor	$v(t) = Ri(t)$	$i(t) = \frac{1}{R} v(t)$	$v(t) = R \frac{dq(t)}{dt}$	R
Inductor	$v(t) = L \frac{di(t)}{dt}$	$i(t) = \frac{1}{L} \int_0^t v(\tau) d\tau$	$v(t) = L \frac{d^2q(t)}{dt^2}$	Ls

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

The capacitor has impedance $\frac{1}{Cs}$, resistor has impedance R and inductor has impedance Ls . So, we can convert the circuit to an equivalent impedance circuit. So, let us convert these. So, here is v_s , this is R_1 R_2 . This is Ls , this is $\frac{1}{Cs}$, and here is v_c . Here is I_1 , and this is I_2 .

So now we will apply the again this impedance law to find the transfer function. So, first we write the equation of motion in s domain. So, here we have some of; so, for mesh one some of impedance around mesh one. So, this is mesh one and mesh 2. Let us say this is mesh one and this is mesh 2 into I_1 minus sum of impedances common to the 2 meshes into I_2 equal to sum of applied voltage about mesh one.

So, we can see that some of impedance around mesh one. So, what is the impedance here? R_1 and R_1 and Ls ; so, in this mesh one there is impedance R_1 and Ls . So, R_1 plus Ls into I_1 minus, sum of impedance common to the 2 meshes. So, here this inductor is common to the 2 meshes. Because this is in mesh one as well as also in mesh 2. So, this minus Ls into I_2 equal to sum of applied voltages around mesh one. So, that is we apply here v_t or here v_s in this mesh one. So, equal to v_s this is equation number one.

Now, for mesh 2 we can write sum of impedance around mesh 2 into I_2 , minus sum of impedances common to the 2 meshes into I_1 equal to sum of applied voltage around mesh 2. So, sum of impedance around mesh 2 is R_2 plus $\frac{1}{Cs}$ plus Ls , into I_2 minus sum of impedance common to the 2 meshes; that is, Ls into I_1 and the sum of applied voltage surround mesh 2. So, about mesh 2 there is no any applied voltage. So, it is 0, this v_c is the measured voltage. This is we are going to measure, this is not some applied voltage.

So now we have we can find I_2 . So, again this we can apply Cramer's rule, because this is a 1×1 plus a 2×2 equal to b_1 and here let us say c_1 and x_1 plus $c_2 \times 2$ equal to b_2 . So, we can apply Cramer's rule. So, I_2 equal to; so, we are going to find I_2 . So, we have R_1 plus Ls and here minus Ls and this is v_s and 0. Upon the determinant R_1 plus Ls minus Ls and this minus Ls R_2 plus $\frac{1}{Cs}$ plus Ls .

So, this is 0 plus Ls into v_s . So, this is equal to Ls into v_s upon Δ . Let us say this is Δ . So, we can find the transfer function I_2 by v_s . So, I_2 by v_s is Ls by Δ , where Δ is given with this determinant.

(Refer Slide Time: 27:10)

Electrical System $I_2(s)/V(s) = ?$

Sum of impedances around Mesh 2 $I_2(s)$ — [Sum of impedances common to the two meshes] $I_1(s) = \left[\begin{matrix} \text{Sum of applied} \\ \text{Voltage} \end{matrix} \right]$

$(R_1 + Ls) I_1(s) - Ls I_2(s) = V(s)$ — (i)

$(R_2 + \frac{1}{Cs} + Ls) I_2(s) - Ls I_1(s) = 0$ — (ii)

$$\frac{Lc s^2}{(R_1 + R_2)Lc s^2 + (R_2 C + L)s + R_1} = \frac{I_2(s)}{V(s)} = \frac{Ls}{\Delta}$$

When we solve this we will find $Lc s^2$ upon $R_1 + R_2, Lc s^2 + R_1 R_2 c + Ls + R_1$. So, this is the final transfer function $I_2(s)/V(s)$. So, here we saw that these 2 examples are taken from the reference books.
