Lecture - 15
Infinite branch cut example

Good morning, welcome to this next lecture on complex variables.

(Refer Slide Time: 00:35)

We were looking at this function which is square root of $z^2 - z_0^2$, which is written as $r_1 r_2$ to the power half $e^{i(\theta + \phi)/2}$. We are looking at the second case where θ lies between 0 to 2π , but ϕ lies between $-\pi$ and π . So, let us examine how the function behaves and again I mentioned $r_1 r_2$ to the power half is just a magnitude. So, it does not bother us. So, let us see what is θ over here, θ over here just above the x axis is 0 , θ is 0 . And what is ϕ ? ϕ is also 0 ; ϕ is also 0 , just above the x axis. What is below? Just below here, what is θ , just below here θ now has to go full round so, θ is 2π .

But, what is ϕ ? ϕ is still 0 ok. If I take a phasor from here and just below the x axis, this angle is 0 , I am begin from $-\pi$ come around ϕ is 0 here. So, ϕ is still 0 . Therefore, you see the difference now. I get e to the power $0 + 0$ by 2 which is 1 , I get e to the power $i\pi$ by 2 which is $i\pi$ so, -1 . So, I have a change in sign now. I have 1 over here -1 over here ok.

For this case e to the power i twice π plus 0 by 2 is equal to e to the power of $i \pi$ which is minus 1 for this lower case, ok. Now, I have a jump in value. If I approach from top I get 1 , if I approached from bottom I get minus 1 for this function. Let us examine in between ok, in between, let us say so now, my z minus z_0 looks like this and z plus z_0 looks like this. So, we will have see what are the θ ϕ values. So, θ for this case is π and ϕ for this case here is 0 , just as before.

If we approach from below, if we approach from below θ for this case is still π and ϕ for this case is still 0 , ϕ is 0 . So, θ π have same values and θ ϕ have same values approaching from above and below. So, this function is continuous here, let us examine what happens here. Here we have θ is equal to; θ is equal to π , θ is equal to π and here ϕ is equal to π also, ok. Because why? ϕ is going from minus π goes around once and comes back here as π . What about below? θ is what is θ here? θ here is π , θ here is π , but ϕ here is minus π , ϕ here is minus π .

So, above you get, I get e to the power of $i \pi$, here I get e to the power $i 0$ so, the function jumps here also. So, interestingly this region is forbidden; this region is forbidden and this region is allowed you can cross here, ok. So, these become the branch cuts, they go off to infinity, they go off to infinity, ok. So, with this knowledge let us look at a problem that involves a branch cut ok, the first problem involving the branch cut.

(Refer Slide Time: 05:35)

BRANCH CUT Problem

$$I = \int_0^{\infty} \frac{dx}{\sqrt{x}(1+x^2)}$$

$$J = \oint_C \frac{dz}{\sqrt{z}(1+z^2)}$$

Complex plane diagram showing a branch cut along the positive real axis from 0 to ∞ . A circular contour C is drawn with radius R and a small inner circle of radius ϵ . The contour is divided into four parts: C_1 (upper arc), C_2 (right vertical segment), C_3 (lower arc), and C_4 (left vertical segment). The angle θ is defined as $0 \leq \theta \leq 2\pi$.

Residue calculation:

$$J = \oint_C \frac{dz}{\sqrt{z}(1+z^2)} = \int_{C_1} + \int_{C_2} + \int_{C_3} + \int_{C_4} = 2\pi i \operatorname{Res}_{z=i} \left(\frac{1}{\sqrt{z}(1+z^2)} \right)$$

Degree of polynomial:

$$z = \epsilon e^{i\theta}, \quad dz = i\epsilon e^{i\theta} d\theta$$

$$\lim_{\epsilon \rightarrow 0} \int_{C_2} \frac{\epsilon e^{i\theta} d\theta}{\epsilon^{1/2} e^{i\theta/2} (1 + \epsilon^2 e^{2i\theta})} \leq \lim_{\epsilon \rightarrow 0} \int_0^{2\pi} \frac{\epsilon^{1/2} d\theta}{\epsilon^{1/2} |1 - \epsilon^2|} = \lim_{\epsilon \rightarrow 0} \int_0^{2\pi} d\theta = 2\pi$$

$$|1 + \epsilon^2 e^{2i\theta}| \geq |1 - \epsilon^2| = \lim_{\epsilon \rightarrow 0} \int_0^{2\pi} \frac{d\theta}{\epsilon^{1/2} (1 - \epsilon^2)} = 2\pi$$

So, we have I , given by again a real line integral, 0 to infinity dx by square root of x and $1 + x^2$ ok; you can see that the integral has to go from 0 to infinity the positive x axis. So, as before we construct another function J , which will be going around a closed contour C and we replace x with z . So, we have z by square root of z into $1 + z^2$ ok. Now, fairly obvious, the cut we are going to take is here ok, we are going to parameterize z in terms of $R e^{i\theta}$ and θ will be between limits 0 and 2π .

So, that now for square root of z , for square root of z , this becomes the cut, as seen before this becomes the cut and as I said we need the portion to be integrated must be part of my contour. So, 0 to infinity must be part of my contour. So, how does that work out ok? So, watch this. We start here, just away from 0 , then we move above the cut; we move above the cut to infinity, ok. So, let this be infinity, then I take a semicircular I mean I said take a circular arc, take a circular arc, the circular, ok.

I go around, I come back here and this is a cut so, I cannot cross. So, now I go along the cut till 0 and I take an epsilon circular contour a radius with epsilon circular contour, means a circular contour with radius epsilon and this here is R going off to infinity and I will join up, ok. So, this is a closed contour now and my closed contour because of square root of z has a branch cut that goes from 0 to infinity, 0 to infinity. And I have isolated poles at z equal to $+i$ and z equal to $-i$, z equal to $+i$, z equal to $-i$. So now, how to solve this problem? So, my J is equal to integral over this closed contour C , ok.

This is my C , it is taken in the positive sense counterclockwise sense and I have dz over square root of z into $1 + z^2$; now I write down the individual portions ok. So, let me call this 1, let me call this circular arc CR as 2, ok, then I have this portion coming from infinity back I will call it 3, then the C epsilon you call it 4. So, I have 4 portions, 4 legs. So, I have the integral going from 0 to infinity upper, above the cut, ok. Then I have this integral over this circular contour with radius going off to infinity, ok. Then I have the portion that comes from infinity to 0 , this portion 3, this portion 1, this portion 2, this portion 3.

And I have lastly this integral over C epsilon limit epsilon tending to 0 ; now there are 2 isolated poles inside the contour; $+i$ and $-i$. So, I will get residues from both $2\pi i$

residue, from i and minus I , ok. So, we immediately if you look at this CR integral, using the degree of polynomial theorem; degree of polynomial theorem, the degree of the denominator is at least 2 greater than the numerator; there is nothing in the numerator, ok. So, CR can be sent to 0 immediately, CR is 0. Now I am left with C_ϵ , C_ϵ . Let us see how C_ϵ integral looks like, ok, on C_ϵ ; on C_ϵ my z is equal to $\epsilon e^{i\theta}$, ok.

ϵ being constant I will move along θ . So, dz is equal to $\epsilon i e^{i\theta} d\theta$, ok. Then, if we substitute this back into J , ok, I have J , I am sorry into C_ϵ . So, I have integral along C_ϵ , ok, we will put the θ limits on that in a minute. So, numerator is dz , which is $\epsilon i e^{i\theta} d\theta$, dz by square root of z is ϵ to the power half $e^{i\theta/2}$ by 2. And then I have, $1 + \epsilon^2 e^{2i\theta}$ and whole thing has limit $\epsilon \rightarrow 0$ and because of the θ definition, we have 0 here, 2π here.

The θ limits on this are $\theta = 2\pi$ and $\theta = 0$ here, ok. Now, the magnitude of this integral, the magnitude of this particular integral is less than equal to the integral of the magnitude and limit $\epsilon \rightarrow 0$. We can informally see that limit $\epsilon \rightarrow 0$, ϵ sits separately on top. So, this will go to 0 or if we still want to do it formally what we do is, we say this is less than, strictly less than limit $\epsilon \rightarrow 0$, integral θ equal to 2π to $\theta = 0$, ok.

Then we replace so, we have ϵ now $e^{i\theta}$ go away, $\epsilon d\theta$ by ϵ to the power of half, $e^{i\theta/2}$ magnitude is 1. Then we replace this with a smaller quantity, ok, we replace this with a smaller quantity, so, that less than strictly holds, ok. So, we know those particular inequalities, which is magnitude of $z = 1 + \epsilon^2 e^{2i\theta}$ is greater than or equal to the magnitude of the magnitude of $z = 1$ minus the magnitude of ϵ^2 , ok.

So, here I have $e^{2i\theta}$ which I want to get rid of. So, what I write as 1 is a magnitude of $1 - \epsilon^2$. What I am saying is that magnitude of $1 + \epsilon^2 e^{2i\theta}$ is greater than or equal to the magnitude of magnitude of 1 which is $1 - \epsilon^2$, ok. So now, what happens is, this is equal to, the integral is equal to limit $\epsilon \rightarrow 0$

integral, here I will switch the integral limits because we need a positive value this modulus we have up here is a positive value. So, we have to switch the integral limits.

So, I get epsilon by epsilon to the power half into 1 minus epsilon square into d theta. This quantity can be pulled out because it is not a function of theta, ok.

(Refer Slide Time: 19:59)

The image shows handwritten mathematical derivations for a complex integral problem. The left side shows the limit of an integral as epsilon goes to 0, and the right side shows the evaluation of the integral using a branch cut and residue theorem.

Left side derivations:

$$\lim_{\epsilon \rightarrow 0} \frac{\epsilon^{1/2}}{\epsilon^{1/2}(-\epsilon^2)} \int_0^{2\pi} d\theta = 0$$

$$J = \oint = \int_{\text{Upper}} + \int_{\text{Lower}} + 0 + 0$$

Diagram of a branch cut in the complex plane along the positive real axis from 0 to infinity. The upper contour is labeled C_ϵ and the lower contour is labeled C_R . The angle θ is shown ranging from 0 to 2π .

$$J = \int_{\text{Upper}} \frac{dz}{z^{1/2}(1+z^2)} + \int_{\text{Lower}} \frac{dz}{z^{1/2}(1+z^2)}$$

Parameterization: $z = re^{i\theta}$, $dz = dr e^{i\theta}$

Right side derivations:

$$J = \lim_{R \rightarrow \infty} \left\{ \int_0^R \frac{dr e^{i\theta}}{r^{1/2} e^{i\theta/2} (1+r^2 e^{2i\theta})} + \int_R^0 \frac{dr e^{i\theta}}{r^{1/2} e^{i\theta/2} (1+r^2 e^{2i\theta})} \right\}$$

$$J = \lim_{R \rightarrow \infty} \left\{ \int_0^R \frac{dr}{r^{1/2} (1+r^2)} + \int_R^0 \frac{dr}{r^{1/2} e^{i2\theta/2} (1+r^2)} \right\}$$

Note: $e^{i\pi} = -1$

$$J = \int_0^\infty \frac{dr}{r^{1/2} (1+r^2)} + \int_\infty^0 \frac{dr}{r^{1/2} (1+r^2)} = 2I$$

$$= 2\pi i \operatorname{Res}(z=i)$$

$$\frac{1}{\sqrt{z}(1+z^2)} = \frac{1}{z^{1/2}(z+1)(z-1)}$$

$$\operatorname{Res}_{z=i} \left(\frac{1}{z^{1/2}(z+1)(z-1)} \right) = \frac{1}{i^{1/2} \cdot 2i} = \frac{1}{2i^{3/2}}$$

And so on the next page, I have, limit epsilon tending to 0 epsilon over epsilon to the power half, 1 minus epsilon square integral with the switched limits d theta. Because, this integral gives me twice pi, but here this epsilon to the power half cancels with epsilon and I get a epsilon to the power half and limit epsilon tending to 0 this goes to 0. Now, what have we achieved? We have J given by this integral over the closed contour and I have the integral on the upper portion plus the integral on the lower portion plus the C epsilon contour which gave 0, plus the CR which gave 0.

Now, let us look at the branch cut once again. We have this upper portion. So, we have a branch cut here, we have the upper portion that goes to infinity. We get into CR and CR 0, we come back over here, then we go to the lower portion, then we close with C epsilon and C epsilon is also 0. So, we now have, J is equal to integral dz over z to the power half 1 plus z square, in the upper part plus integral lower dz over z to the power half 1 plus z square. Now, let in both these cases, z be equal to r e to the power of i theta and dz is equal to dr e to the power of i theta because, theta is a constant on each of these portions.

So, now J becomes equal to limit R tending to infinity, integral 0 to R , dz which is $dr e$ to the power of $i\theta$ by z to the power half which is r to the power half e to the power of $i\theta$ by 2 into $1 + z^2$, $1 + r^2 e$ to the power twice $i\theta$; this is the upper portion, plus integral R to 0 , $dr e$ to the power of $i\theta$ by the same expression, r to the power half e to the power of $i\theta$ by 2 , $1 + r^2 e$ to the power of twice $i\theta$. Here, θ is equal to 0 , this is $\theta = 0$, $\theta = 0$ here, and here θ is equal to twice π .

So, here θ is equal to twice π . So, we get J is equal to, limit R tending to infinity, 0 to R , $\theta = 0$. So, we get dr over r to the power half, e to the power $i0$, $1 + r^2$, plus integral R to 0 , here θ is 2π . So, I get again dr divided by R to the power half, e to the power of i twice π by 2 , into $1 + r^2$. This gives me e to the power of $i\pi$, which is a minus 1 and I can use this minus 1 and switch the limits on the integral, ok. So, if I do that, now integral 0 to infinity dr by r to the power half, $1 + r^2$, plus again integral 0 to infinity, dr by r to the power half, into $1 + r^2$.

So, this is essentially twice the integral I want, this is equal to 2 times I which should be equal to twice πi times the residue at plus and minus i . Now, for the residue ok, the function we have is given by, 1 over, function we have is given by 1 over root z , into $1 + z^2$. And so, we write this as 1 over z to the power half, $z + i$ into $z - i$.

So, the residue at plus i ; residue at plus i is given by 1 over z to the power half $z + i$ into $z - i$, multiplied by $z - i$, evaluated at either z equal to e to the power of $i\pi$ by 2 or z equal to i . So, we get a cancellation and for z to the power half, I use z equal to e to the power $i\pi$ by 2 . So, 1 over e to the power of $i\pi$ by 4 and here I use z equal to i so, I get twice I , ok.

(Refer Slide Time: 29:47)

Residue at $-i$

$$\frac{(z+i)^{1/2}}{z^2(z-i)} \Big|_{z=-i} = \frac{1}{e^{i3\pi/4}(-2i)}$$

$$= \frac{2\pi i}{2i} \left(\frac{e^{-i\pi/4} + e^{i\pi/4}}{2} \right) = 2\pi \cos \pi/4 = \frac{2\pi}{\sqrt{2}}$$

$$\oint \Gamma = \frac{2\pi}{\sqrt{2}} = \frac{\pi}{\sqrt{2}}$$

Residue Contribution

$$= 2\pi i \left(\frac{1}{e^{i\pi/4} 2i} + \frac{1}{e^{i3\pi/4} (-2i)} \right) e^{-i\pi}$$

$$= 2\pi i \left(\frac{1}{e^{i\pi/4} 2i} + \frac{1}{2i e^{-i\pi/4}} \right)$$

For the residue at minus i, I have z plus i divided by z to the power half, into z plus I, into z minus I, evaluated at z is equal to e to the power of i 3 pi by 2 or z equal to minus i. Let me explain why I have this particular expression ok. I have a branch cut; I have a branch cut and on the branch cut z is written as r e to the power of i theta, theta varying from 0 to twice pi.

So, theta varies it is 0 over here, this pi by 2 over here, it is pi over here, it is 3 pi by 2 over here and so forth. Now, when evaluating the part of the function which has given us the branch cut, we have to respect this definition so, that we do not go incorrect. I have poles at plus i and minus i. So, if I use minus i for this, as I am doing for this part of the function, if I say minus i to the power half then the square root has 2 values; I do not know which value to choose. So, it is better to use the branch cut definition, z here is e to the power i 3 pi by 2 and z here is e to the power of i pi by 2.

For the other part it does not matter, you can use z equal to i here z equal to minus i here, but for the part that is causing the branch cut, you have respect this definition, ok. So now, this gives me 1 over e to the power i 3 pi by 4, into minus twice i. So, the residue contribution; residue contribution is equal to twice pi i, into 1 over e to the power of i pi by 4 twice i, plus 1 by e to the power of i 3 pi by 4, into minus twice i, ok.

Now, here I will multiply the numerator and denominator by e to the power minus i pi, denominator by e to the power of minus i pi. So, that I get twice pi i, into 1 over e to the

power of i π by 4 twice i , now e to the power i π gives me a negative. So, I get a negative and that negative cancels this negative so, the negative is gone. So, I get a plus 1 by twice i , but this e to the power i π by 4 and minus i π gives me e to the power minus i π by 4.

And so, I have twice π I, take twice i outside, e to the power of minus i π by 4, plus e to the power i π by 4, ok. If I divide this by 2, multiply by 2, cancel twice i twice i , I get π into $2 \cos \pi$ by 4; this is equal to twice π by root 2 and on the left I had twice i 2 times i is now is equal to twice π by root 2. And so, the answer is π by root 2 ok. So, with this I close today's lecture.

Thank you.
