Lecture - 07
Implications of Cauchy Goursat Theorem, Cauchy Integral Formula

Good morning and welcome to this next lecture on a Complex variables.

(Refer Slide Time: 00:41)

Last time we had seen the Cauchy Goursat theorem. We had seen this in some detail, so I will not repeat it. In brief it says, if f of z is analytic on and inside a simple closed contour named C , then integral over the closed contour f of z dz is equal to 0, the contour navigated in the positive anti clockwise direction.

Now, this can be very easily extended to simply connected domains; simply connected domains because interiors of closed contours are involved. So, we can also say that if f of z is analytic; if f of z is analytic throughout a simply connected domain D , then integral over C a closed contour, f of z dz is 0 for every closed contour; every simple closed contour C lying in D . It's a pretty straightforward extension to simply connected domains.

Now, this has very important consequences. Now consider this situation. We have a closed contour C taken in the positive sense. And suppose I have two more regions. Let

us call this contour C_1 . Call this contour C_2 . Let us not yet give any directions to them. So, this is the extension of Cauchy Goursat theorem or the implications of Cauchy Goursat theorem. So, if now I break this situation in the following way: let me first say that a function f of z is now analytic on C , on C_1 and C_2 and in between the region that exists between C , C_1 and C_2 . The regions inside C_1 and inside C_2 are excluded, ok.

So, now I am going to apply the Cauchy Goursat theorem here. Before that what I do is I close these contours in the following manner. I will call this the upper part ok, so let me draw this again, ok. I will call one piece the upper. This is C_1 upper, C_1 lower, C_2 upper, C_2 lower, ok. The direction on C upper and this part is C lower. And I take I call this bit L_1 . I call this bit L_2 , I call this bit L_3 . the directions are given. I am sorry this will be this way.

So, I have two contours now: C upper comes this way gets into L_1 ; L_1 joins C_1 upper, joins L_2 ; L_2 joins C_2 upper, joins L_3 and then I close. Similarly, I have another closed contour with C lower, so we will see what happens now. So, I say that this function f of z , ok, with integrals C upper, plus L_1 , plus integral C_1 upper, plus integral L_2 , plus integral C_2 upper, plus integral L_3 , ok, this forms this closed contour, this forms this closed contour, ok.

Now, given this statement that f of z is analytic on C ; on C_1 ; on C_2 and in between, ok. So, I have the statement made for Cauchy Goursat theorem: a function f of z is analytic on and inside a closed contour. All these little bits form this closed contour on the upper side. So, now, this integral on f of z is equal to 0, of $z \, dz$ is equal to 0, ok.

So, let us see now I have gone so far into the border. Let me just say here, that is equal to 0; is equal to 0. Similarly, for the lower side what I will do? I will take integral C lower this one, then I have L_3 , but in the opposite direction. So, I will take minus L_3 here, minus L_3 , ok, then I take C_2 lower; I take C_2 lower, plus integral C_2 lower, ok, then I have L_2 , in the opposite direction. So, I do minus L_2 ; L_2 , then I have C_1 lower, plus C_1 lower, then I have L_1 in the opposite direction minus L_1 , ok.

So, these integrals, these line integrals again form an integral of f of z on a closed contour which is on the lower side. Now, the function f of z is well behaved in these regions between the circles, ok. So, here if I have an integral going rightward and an integral going leftward, they will cancel out, because the function is well behaved. So

this is also 0, f of z dz here is also equal to 0. Now, I am going to add the two. If I add the two, plus L_3 and minus L_3 cancel out, plus L_2 and minus L_2 cancel out; plus L_2 minus L_2 cancel out, similarly plus L_1 minus L_1 cancel out, ok.

So, what am I left with? I am left with C upper and C lower, which forms a counterclockwise, so that makes it integral counterclockwise C , ok. Then I have C_1 upper and C_1 lower, which is plus integral clockwise C_1 . Then I have plus integral C_2 upper and C_2 lower, which makes it again a clockwise closed contour C_2 . So, this set of integrals operating on f of z dz equal to 0.

Handwritten notes on a digital whiteboard showing the derivation of the Cauchy Integral Formula. The notes include mathematical equations and diagrams of contours.

Left side equations:

$$\oint_C f(z) dz = -\oint_{C_1} f(z) dz - \oint_{C_2} f(z) dz$$

$$= \oint_{C_1} f(z) dz + \oint_{C_2} f(z) dz$$

Diagram showing a large contour C with two smaller contours C_1 and C_2 inside it. Arrows indicate the direction of integration.

Below the diagram, it says "Deform Contour".

Right side equations:

Cauchy Integral Formula.

Let f be analytic everywhere within and on a SCC C , taken in the positive sense. If z_0 is any interior point to C , then

$$2\pi i f(z_0) = \oint_C \frac{f(z)}{z - z_0} dz$$

Diagram showing a contour C with a point z_0 inside it.

$$\oint_C \frac{f(z)}{z - z_0} dz = \oint_{C_0} \frac{f(z)}{z - z_0} dz$$

Diagram showing a small contour C_0 around z_0 .

Below the diagram, it says "Deform Contour".

$$\oint_{C_0} \frac{f(z)}{z - z_0} dz = f(z_0) \oint_{C_0} \frac{dz}{z - z_0}$$

Diagram showing a small contour C_0 around z_0 .

Now, what I will do, we need to go to the next page. I will bring C_1 and C_2 to the other side. So, I will have integral counterclockwise on the C , f of z dz is equal to a negative integral clockwise C_1 , f of z dz , negative integral clockwise C_2 , f of z dz . Now, if I change the signs of this, I can change the directions of the contours. So, I change the sign and change the contour direction, now this is made counterclockwise C_1 , f of z dz plus integral control clockwise C_2 , f of z dz .

Now, you see the integral of f of z on the outermost contour is the sum of integrals of f of z along C_1 and C_2 which are contours inside, ok. So, if I have a large number of these regions inside C , where the function interior to these contours is not analytic, but its analytic on those contours and between the outer contour and these circles. Then the

integral over the outermost contour is equal to sum over the integrals of all the contours inside.

Now, a further bigger consequence is, suppose there was only one. So, this is the outermost contour C traversed in the counterclockwise direction and there was one inner contour let us say C_0 . And if a function was analytic between these two contours and on the two contours, but not inside, then the integral counterclockwise on C , $\oint_C f(z) dz$ is equal to the integral counterclockwise C_0 , $\oint_{C_0} f(z) dz$. This is very big, this result is very big and very significant.

What it implies, is that suppose I have an integration to be done of this form on a closed contour and perhaps the contour is somewhat inconvenient or something, then I have a singularity inside somewhere, I have a singularity, suppose this is a situation some contour that is has an odd shape.

And I have a singularity inside and I am supposed to do the contour integral on C ok. What I can do is I can deform this contour into whatever convenient form I want perhaps a nice circle and take it down as long as I do not touch the singularity. So, I can deform this contour C into C_0 of any shape that I want as long as I do not touch the singularity. So, this integral, outer integral C , the value $\oint_C f(z) dz$ will be identical to integral over the convenient contour of my choice C_0 , $\oint_{C_0} f(z) dz$ ok.

So, we can deform the contour as long as we do not touch a singularity or cross a singularity. Now, this can be formalized and the formal statement is there in the book by Churchill. Now, let us proceed to the next theorem ok. The next theorem is called Cauchy integral formula, ok. In the spirit and with the pace I am going I will give a very sketchy proof of this. The rigorous proof is there in the book by Churchill and Brown ok. So I will refer to that book.

So, what does this Cauchy integral formula say? Let f be analytic; f be analytic everywhere within; everywhere within and on a simple; on a simple closed contour C , taken in the positive sense, counterclockwise sense, ok. If z_0 is any interior point to C , then $2\pi i \oint_C \frac{f(z)}{z - z_0} dz$ is equal to the integral over the closed contour taken in the positive sense, $\oint_C \frac{f(z)}{z - z_0} dz$.

So pictorially, there is this contour C , closed contour C taken in the positive sense and there is this point z_0 , ok. So, let us see how, so as I said I will do a not so rigorous sketchy proof. The epsilon delta type proof is where in Churchill. so I would recommend that students look at it. So, now, let me enclose this point z_0 by a small circular contour and call it C_0 taken in the counterclockwise sense. So, now, from what we have seen previously, our function f of z is analytic everywhere on C on C_0 and in the in between region.

So, this particular integral f of z by z minus z_0 dz , counterclockwise on C is identical to the integral taken counterclockwise on C_0 , f of z by z minus z_0 dz . Now, from the earlier portion we have seen, that I can go as close as possible to the singularity, as long as I do not cross it or touch it. So, here also I can go closer and closer; and closer and closer to z_0 , as far as possible without touching z_0 , ok.

And since f of z is a well behaved function; f of z is a well behaved function and suppose f of z is analytic and hence continuous, what will happen is as C_0 is made smaller and smaller around z_0 , it will acquire a constant value of f at z_0 or it will approach that value, because f of z is continuous.

So, on the right side I will make C_0 tighter and tighter around z_0 . So, that as f of z approaches or z approaches z_0 , I can put f of z_0 outside the integral. It is acquiring a constant value as I make C_0 tighter. So, this is now dz over z minus z_0 . As I say this is a rough proof ok, but it is useful, ok. So, now, what I have is, f of z_0 and an integral over C_0 , dz by z minus z_0 .

So, what is this? This is the value of the integral we began, f of z by z minus z_0 dz over the original contour C which we should not forget. We are trying to compute the value of this particular integral, ok. So, now, we have to evaluate this part; we have to evaluate that part, ok.

(Refer Slide Time: 25:15)

Handwritten mathematical derivations on a digital whiteboard. The left side shows the derivation of the Cauchy Integral formula for a circular contour. It starts with a contour integral of $\oint_{C_0} \frac{dz}{z-z_0}$ around a circle C_0 , then parameterizes $z-z_0$ as $Re^{i\theta}$, leading to an integral of $i d\theta$ from 0 to 2π , which equals $2\pi i$. This is then used to derive the Cauchy Integral formula: $\oint_C \frac{f(z) dz}{z-z_0} = 2\pi i f(z_0)$. The right side is titled "Extensions to C.I.F." and shows the derivation of the Cauchy integral formula for an interior point z by taking the limit as $\Delta z \rightarrow 0$ of $\frac{f(z+\Delta z) - f(z)}{\Delta z}$, resulting in the formula $f(z) = \frac{1}{2\pi i} \oint_C \frac{f(s) ds}{(s-z)^2}$, noting it is "bound to exist".

So, let us see what is integral over C $0 dz$ by z minus z_0 , ok. I say that we are going around a small contour around z_0 . Let us say over a radius R . So, my z minus z_0 I will replace with $Re^{i\theta}$. z then is equal to z_0 plus $Re^{i\theta}$. Then dz is equal to: z_0 is constant, R is a constant, so $Rie^{i\theta} d\theta$.

Now, I replace everything in z with everything in θ and so my limits on θ become 0 to 2π , 0 to 2π . dz is $Rie^{i\theta} d\theta$ divided by z minus z_0 which is $Re^{i\theta}$. So, R goes out. $e^{i\theta}$ goes out. $i d\theta$ from 0 to 2π is i times twice π , ok.

So, if we add what is on the previous page, the integral I want: counterclockwise over C , $\oint_C \frac{f(z) dz}{z-z_0}$ is equal to $2\pi i f(z_0)$. This is called Cauchy integral; Cauchy integral formula, formula. Now, the Cauchy integral formula has consequences, ok. Extension, extensions to Cauchy integral formula.

Now, what is the extension? So, what we say here is: let f be analytical within and on a simple closed contour by the name C and here let z be any interior point ok. Then we do it, we write this in a different set of variables. So, $2\pi i f(z)$ is equal to, integral closed contour C , $\oint_C \frac{f(s) ds}{s-z}$. We have written it in terms of z . Earlier we wrote it in terms of z_0 , ok.

Now, watch what happens. What I will do is, I will take this limit Δz going to 0, $f(z + \Delta z) - f(z)$, divided by Δz , ok. How does what happens on the right hand side? Obviously, I will get the limit Δz going to 0. Then I have $\frac{1}{2\pi i}$. Then I have the integral over the closed contour C and here I have $\frac{1}{S - z - \Delta z}$, into $f(S) dS$, divided by Δz , ok.

This is for $f(z + \Delta z)$; this is for $f(z)$, ok. So, now, what happens. Let me write it here: is equal to limit Δz tending to 0, $\frac{1}{2\pi i}$ integral counterclockwise C . I do the LCM of this and what I get is, $f(S) dS$ by $S - z - \Delta z$, into $S - z$. I have taken an LCM of this and brought $f(S) dS$ on the top. The LCM just gives me Δz on the top which cancels with this Δz in the denominator here.

Now, the point to be made here is that, $f(S)$ is well behaved everywhere inside. So, I can straight away take the limit Δz going to 0 in here. It is not going to cause any issues. I am not violating singularities or any creating any singularities. So, Δz can be straightaway taken in. So what I get is, $\frac{1}{2\pi i}$ integral counterclockwise C , $f(S) dS$ by $S - z$ whole squared. And this is bound to exist ok; this is bound to exist ok. We will extend this further for a general case. So, I will stop here for today we will continue in the next class.

Thank you.
