Bohr Model for the Spectrum of Atomic Hydrogen

(Refer Slide Time: 00:00)

The image shows a digital notebook page with a diagram of an atom and a derivation. The diagram depicts a central nucleus labeled 'Fe' with a '+' sign, and two electrons labeled 'e-' orbiting in a circular path. A red box highlights the text 'Newton's second law'. Below it, the equation $-F_e = \frac{e^2}{4\pi\epsilon_0 r^2} = \frac{mv^2}{r}$ is written. Arrows point from the terms in the equation to their physical meanings: $-F_e$ is labeled 'electrostatic force charge', $\frac{e^2}{4\pi\epsilon_0 r^2}$ is labeled 'electron mass', and $\frac{mv^2}{r}$ is labeled 'centripetal acceln'.

The image shows a digital notebook page with mathematical derivations. At the top, the terms 'electrostatic force charge' and 'centripetal acceln' are repeated. Below, the kinetic energy of an electron is derived: $T_e: \text{KE of electron} = \frac{1}{2}mv^2 = \frac{e^2}{8\pi\epsilon_0 r}$. Then, the potential energy is derived: $V_e \text{ potential energy} = \int \frac{e^2}{4\pi\epsilon_0 r^2} dr = -\frac{e^2}{8\pi\epsilon_0 r}$.

So, welcome to lecture number 12 of Statistical Thermodynamics. So, as we saw that the hydrogen spectra could be explained by the Bohr's model. Let us see how that can be explained

by the Bohr's model. Let us take a very simple system. This is the orbit of electron and this is central nucleus, which has got the positive charge, plus and minus and the radius is r .

Then electron is moving in this particular direction, the velocity we need, let us call that v . And of course, there is an inward force because the electron is moving, let us call that inward force as F_e . So, what we do, this is a very simple system in which there is a nucleus and let us take the hydrogen for example. So, this is the nucleus which is positively charged, the electron is moving around the nucleus. It is like a single electron kind of a system because of hydrogen. It moves with a velocity v .

So, what we do is that we apply Newton's second law here to this particular system. So, let us write the force F_e , F_e is nothing but an electrostatic force because it is a positive-negative charge, and then that electrostatic force is given as e^2 by $4\pi\epsilon_0 r^2$ as electrostatic force, e is nothing but a charge and this should be equal to the centripetal force, which is given as $m_e v^2$ divided by R .

So, basically this particular part of the term is called a centripetal acceleration. This is the electron mass. So, you have, what we have over here we apply Newton's second law to this particular system which has got an electron which is rotating around the nucleus which is composed of a proton, the velocity of electron is v , so there is an electrostatic attraction which is given by F_e and then of course, there is a centripetal acceleration which basically balances this electrostatic force of attraction.

So T_e , if I project T_e as the kinetic energy of the electron that is equal to half $m_e v^2$. m_e is basically the mass of electron which is also equal to e^2 by $8\pi\epsilon_0 r$ as you can see from this particular expression just add a half to it and you can see that this is how it halves because of this balance we can write it like this.

So, therefore, V_e which is basically a potential energy, this is different and is not the velocity potential energy that is given by, so this is the kinetic energy of the electron that is a potential energy of electron. It is from infinity to R if you bring an electron in, this e^2 by $4\pi\epsilon_0$ naught, dr by r^2 . This is the force field is the electrostatic force field so this is the potential energy which is equal therefore to the minus e^2 divided by $8\pi\epsilon_0$ naught into r .

higher orbits lower orbits

This is the potential energy so the total energy of electron is given as the total energy e , T_e plus V_e so it is the kinetic energy plus the potential energy, if you add the 2 it will be e square by 8π epsilon naught r . This is the total energy of an electron which is orbiting around at nucleus. So, what did we do? We first balanced the electrostatic force with the centripetal force and then we calculated the kinetic energy of the electrons and we calculated the potential energy of the electron.

This is the energy that is spent to bring the electron from infinity to a radius R . This is the central definition. So, this should be the energy of the electron. Now, Bohr's had the following postulates. So, these are postulates you remember, so he said that the angular momentum, r is

quantized, where this is nothing but $n h$ into 2π where n is equal to 1,2,3, so n is an integer as we all know that is the integer representation. So, the angular momentum is quantized. It basically says angular momentum is quantized.

This is the first postulate of Bohr's, the second one is that transition from lower to higher orbit is given by we already saw this. This is a wave number is energy e_n minus energy e_m divided by hc this is basically ΔE .

This is the higher energy and this is lower orbit. so, what did Bohr did apart from this he said that the angular momentum is quantized and it is given by this particular form which is $n h$ by 2π , n are integers, so, naturally this is quantized. So, this can have discrete values only and transition from higher to lower orbit is given by this which is nothing but a differential of energy this is ΔE basically this is higher orbits and these are the lower orbits. Armed with this, what will be the form for v ?

(Refer Slide Time: 08:04)

The image shows a digital notebook interface with a dark blue header. The title bar reads "Untitled Notebook (32)". The notebook page is yellow and contains handwritten text in blue ink. At the top, there are two labels: "higher orbits" and "lower orbits", with arrows pointing downwards from each. Below these, the following equations are written:

$$\therefore v = \frac{nh}{m_e r}$$
$$\therefore T_e = \frac{1}{2} m_e v^2$$
$$= \frac{1}{2} m_e \left[\frac{nh}{m_e r} \right]^2$$
$$= \frac{e^2}{8\pi\epsilon_0 r^2}$$

On the left side of the notebook, there is a vertical black bar with white text that reads "Statistical Thermodynamics for Engineers" and "Lec 12". In the bottom right corner, there is a small video feed showing a person's face.

Statistical Thermodynamics for Engineers
Lec12

Handwritten equations in the notebook:

$$r = \frac{4\pi\epsilon_0 \hbar^2}{m_e e^2} n^2 \quad n=1,2,3,\dots$$

$$\therefore E_n = \frac{-e^2}{8\pi\epsilon_0} \frac{m_e e^2}{4\pi\epsilon_0 \hbar^2 n^2}$$

$$\text{or } E_n = \frac{-m_e e^4}{8\epsilon_0^2 h^2 n^2}$$

Let us look at v . Therefore, v is equal to $n h$ divided by $m e r$ because of the quantization. From the quantization we can say v is equal to $n h$ by $m e r$ that is exactly what we have written. So, therefore T_e is equal to half $m e v$ square, which is further represented as r , $m e$ let us put it as $n h$ by $m e r$ square.

Now if you substitute from the previous expressions it will be e square by $8 \pi \epsilon_0$ naught r and r therefore, if you equate the 2 will be given by $4 \pi \epsilon_0$ naught h bar square divided by $m e e$ square into n square. Basically we equated the 2 and we have substituted for V which is given by this particular form. So, this additional form, if you could look at it here from here it was it was not quite evident that how the quantization comes into the picture.

Here you can be clear that because the angular momentum was quantized this readily offers that expression to calculate V and V can be now further substituted in the kinetic energy term. And therefore, now equating with the existing expression for kinetic energy, which we already did over here. Taking this and equating these two, we get a definition for r , where n is equal to 1,2,3. So, as you can see r is naturally quantized.

Therefore, E_n the energy at any particular at n th energy level is therefore, 2π naught $m e e$ square divided by $4 \pi e$ naught h bar square n square that comes from the expression that we just now saw here or in other words E_n is given as minus $m e e$ to the power of 4 divided by $8 \epsilon_0$ naught square h square n square. So, this is the energy at any particular energy level and it is given by this particular expression that we have over here.

Now, if the energy is written in this form, wave number space form is given as minus $m e e$ to the power 4 divided by $8 \epsilon_0$ naught square $c h$ cube into 1 over n square. This 1 over n square is very important because this is where the quantization comes, therefore, $\gamma_n m$ is given as $m e e$ to the power 4 divided by $8 \epsilon_0$ naught square $c h$ cube then let us change the font (())(12:07) 1 over m square minus 1 over n square.

This particular guy that you see over here is supposed to be the Rydberg constant. What did and it indeed turns out to be a very accurate estimate of the right words constant. As we can see. Therefore, in this particular expression that this RH is now represented by this, so, just let us do a very quick recap. What happened was that we first ask this very simple system of an electron rotating around the nucleus we applied Newton's second law in which the electrostatic force was balanced by the centripetal acceleration and then we pass the kinetic energy of the electrons is given by this and the potential energy is given by this form.

This happens because in a conservative system, this is the energy that is you bring the electron from infinity to all the way up to r and that is what gives you the potential energy. That is what gives the potential energy for a conservative system from infinity to r . Now, that gives the total energy. The total energy is nothing but the sum total of the kinetic energy and the potential energy which is given as this.

So, then we move on now that we have got this all sorted out then we went to the Bohr's postulates. In Bohr's postulate what did Bohr's says that the angular momentum is also

quantized and it is given in this particular form where n is basically the integer to which the quantization happens and transition from lower to higher orbit is given by this. This is nothing but ΔE . Therefore, using this particular expression now, which is the quantization of angular momentum, we found an expression for V which is the velocity.

So, the kinetic energy is therefore given as this and kinetic energy already found is given in this particular form. So, equating these two we found that what will be the allowed radii, the allowed radius of the orbits. You can write it as radii of allowed orbits. This happens through the quantization of N equals to 1, 2, and 3. You cannot have all orbits, this is given in discrete forms. Any energy can be now if you look at this particular expression, the total energy. The total energy is substitute the expression for R .

In that expression that basically you put this here and you get this expression for energy. Now, once you now you can this is just algebraic manipulations and then once you see the differential so when you normalize the energy this is it comes into the wave number space and then you find out what is a wave number for a transition, an allowed transition. So, therefore, this constant that sits in front should be the Rydberg constant and this is exactly what it is, because this matches with experimental data.

You can understand what we did over here if you do not, the energy let us write this expression between so that you get an idea that when we say energy. What does it exactly mean? The energy if you recall was given as $-\frac{e^2}{4\pi\epsilon_0 r}$, $\frac{8\pi\epsilon_0}{r}$. And r we found out was given as $\frac{4\pi\epsilon_0 \hbar^2}{me^2 n^2}$.

Now, if you substitute this here, that is how we get the energy of any n th energy level as me^2 to the power of 4, $\frac{8\epsilon_0}{n^2}$ $\frac{h^2}{n^2}$. This is how you get the final expression. so, you just put this right here. So, that is how you get the energy.

So, what we have got over here we have got an idea of the allowed radius, the allowed orbit, radii of the orbit and we have also got an expression for the energy. Energy of each energy level or the n th energy level has actually got this energy and this is quantized and it is given in terms of electron charge, electron mass, then the ϵ_0 permittivity of free space H , the Planck's constant etcetera. That is a very clear idea now that what is going on.

(Refer slide Time: 17:39)

The image shows two screenshots of a digital notebook titled "Untitled Notebook (32)". The notebook is open to a page with handwritten notes in blue ink. The top screenshot shows the following text: "De-Broglie hypothesis", "light can be particle or wave.", "matter can be particle or wave too.", "linear momentum of a parallel light beam", and the equation
$$P = \frac{E}{c} = \frac{h\nu}{c} = \frac{h}{\lambda}$$
 with a note below it: "↳ linear momentum of a single photon". The bottom screenshot shows the same equation and note, followed by "for matter waves", the equation
$$\lambda = \frac{h}{p} \rightarrow \text{momentum of particle.}$$
, the value
$$h = 6.6261 \times 10^{-34} \text{ J}\cdot\text{s}$$
, and the note " λ : very small for coarse matter". Both screenshots include a vertical sidebar on the left with the text "Statistical Thermodynamics for Engineers Lec12" and a small video feed of a person in the bottom right corner.

Now, let us quickly take a small you know detour and talk about De- Broglie hypothesis. What did De Broglie actually do? So, as we saw that light can be both particle or a matter. Can be particle, sorry, wave not matter. So, matter can be, matter can be particle or wave too. Electron can also behave like a wave.

The linear momentum of parallel light beam. P is given as epsilon by C, E by C, E as we already know is the energy that is carried this is equal to H by lamda. This is like the linear momentum of a single photon. For matter waves, this lambda should therefore be given as H by P, h is

Planck's constant, p is the momentum of the particle. So, this is like an analogy. So, since the h is about 6.6261×10^{-34} , Joule second.

The momentum of a particle will be kind of small, so, λ is usually very small for large matter. So, that means when you move to the wave length associated with you is so small that it is almost undetectable. This is definitely not the case with fundamental particles.

$$R_{H \text{ expt}} \approx 109678 \text{ cm}^{-1}$$

De Broglie wavelengths

a) golf ball $m = 0.04 \text{ kg}$
 35 m/sec

b) electron in Bohr
hydrogen atom

For example, in an electron, λ is nothing but h divided by $m_e v$, which is given as $2\pi r$ into n . so, it is an integer. This λ now becomes an integer fraction of its orbitals. This is

rather interesting. So, this is for an electron. So, large matter wave forget about that let us talk about electrons. So, electrons if we do then if you substitute all the quantities over here, you get this something like this.

And then as you can see that λ of an electron is basically an integer fraction of its orbitals circumference. This is quite good. So, this is what we mean by when we actually have this kind of a situation. So, what happened was and also people calculated the Rydberg constant from the Bohr's model, it turned out to be about 109743 centimeter inverse, compare it to the experimental calculation of the Rydberg constant is 109678 centimeter inverse.

So, these are kind of very close to each other. That is what it is. So, we could cast we could explain more or less the hydrogen spectrum with the Bohr's model by using the Bohr's postulate and stuff like that. So, also the, you know, the discrete energies can be always can be well represented pictorially also using the Bohr's model, but in general, despite its rather ad hoc linkage between classical and quantum concepts, the Bohr's model was very successful, it provided for the first time, a robust explanation of the existence of stable electronic orbits in an atom, and its predictions actually matched with experimental spectra of atomic hydrogen.

It could also predict the Rydberg constant. So, all these things were the good part of the Bohr's model, though, it feels a little ad-hoc because of the postulates because of the way that it is stitched together, but he could explain the discrete energies, he could explain the transitions, he could explain a fundamental constant, he could also explain that why this electronic orbits are going to be very stable. So, this was more or less consistent, I should say, a consistent theory which uses classical mechanics and tries to explain from the quantum mechanical concepts that we have over here.

And we also saw the de-Broglie hypothesis, that you know, by what is what is matter wave and how matter wave is associated for large matter, the matter wave is very small not so, when you are actually doing with an electronic orbit of an atomic hydrogen for example. We could actually get these 2 things.

Now, let us do a very quick problem say the de-Broglie wavelength rather destroyed by an example, say A a golf ball with the mass is about 0.04 kg. It starts at a velocity of 35 meter per

second. Then of course, the electron. The electron in Bohr hydrogen atom. This is just a quick calculation just to show.

$p = m_e v = (9.109 \times 10^{-31})$
 $(2.19 \times 10^6 \text{ m/s})$
 $= 1.99 \times 10^{-24} \text{ NS}$

$\lambda = \frac{h}{p} = 3.33 \times 10^{-10} \text{ m}$
 $= 3.33 \text{ \AA}$ ←
 First order 1.06 \AA

46 of 46

So first what we do the linear momentum of the golf ball is basically mv which is equal to 0.04 into 35 , which is about 1.4 Newton second. So the de-Broglie wavelength, the λ becomes h by p , which is 6.626 into 10 to the power minus 34 joule second divided by 1.4 Newton second which gives you 4.73 into 10 to the power of minus 34 meters.

You can see how small this wavelength is, very small indeed, and more massive objects will have even lower wave length. So, minus 34, this is much smaller than the size consequently, that matters waves do not have any influence on the dynamics, that is why you could hit a golf ball and you could predict where it is going to go, well, the fluid mechanics part of it can be complicated, but technically it is still deterministic. So, you can say where the ball will go.

On the other hand, if we look at the electron, electron p MeV is 9.109×10^{-31} this is the electrons mass into 2.19×10^6 meter per second that is velocity. So, this gives you 1.99×10^{-24} Newton's second.

The lambda for the electron will be h by p . So, that is about 3.33×10^{-10} meter. So, it is about 3.33 angstrom which is comparable. So, Bohr's first radius is about 1.06 angstroms. So, these 2 are kind of comparable, they are in the same ballpark, therefore, we must expect quantum effects for atomic hydrogen which we saw in its initial spectrum.

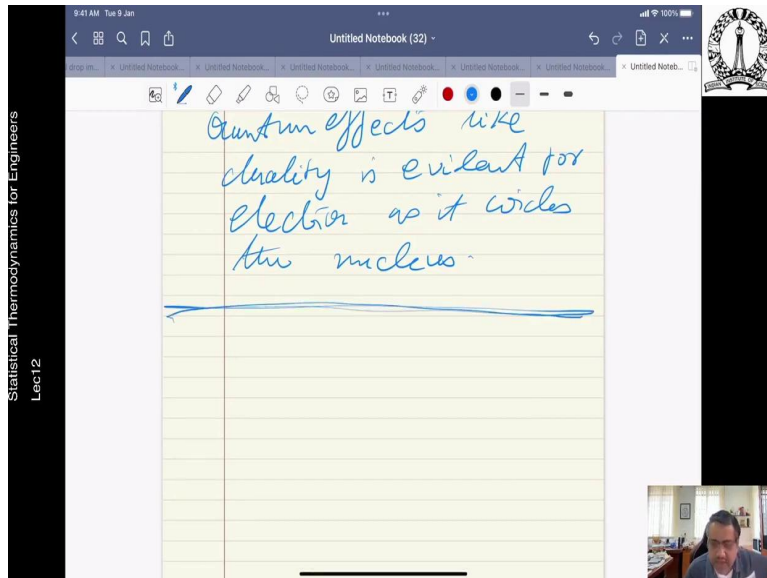

(Refer slide Time: 27:00)

The screenshot shows a digital notebook interface with the following content:

- Top bar: "9:41 AM, Tue 9 Jan" and "Untitled Notebook (32)".
- Handwritten calculations:

$$p = m_e v = (9.109 \times 10^{-31}) (2.19 \times 10^6 \text{ m/s}) = 1.99 \times 10^{-24} \text{ NS}$$

$$\lambda = \frac{h}{p} = 3.33 \times 10^{-10} \text{ m}$$
- Comparison: A box highlights the value 3.33 \AA with an arrow pointing to the text "First radius (1.06 \text{ \AA})".
- Bottom section: "Quantum effects like duality is evident for".
- Page number: "46 of 47" in the bottom left corner.
- Bottom right: A small video feed showing a person's face.

Quantum effects like this duality is evident for electron as it circles the nucleus. So, you cannot avoid it because these 2 are the similar order. Almost close, one is one third of the other, so, this is just to show that why the matter waves are like that and we have provided a more or less good understanding that how the Bohr's model though ad-hoc is actually successfully explaining many of the things in the hydrogen spectrum.

But, however, we can still see that there is a lot of lacunae, there is no clear cut theoretical perspective or theoretical framework as such, as such which we need to go to Schrodinger's wave equation and that we will do in a heuristic fashion, not in a kind of rigorous fashion and we will see how the Schrodinger's wave equation can be used as a first stepping stone to explain the entire Quantum mechanics. See you in the next class. Thank you.
