SCHMID'S LAW

(Refer Slide Time: 00:06)

So, in the last video we discussed the important concept of resolved shear stress and critical resolved shear stress. Related to this critical resolved shear stress there is a very interesting law called Schmid's law.

(Refer Slide Time: 00:25)

SCHMID'S LAW

$$\tau_{RSS} = \sigma \cos \phi_N \cos \phi_D$$

↓ ↓

$$\tau_{CRSS} = \sigma_y \underbrace{\cos \phi_N \cos \phi_D}_{\text{Schmid factor}}$$

Depends upon the orientation of stress axis with respect to the slip system.

A change in orientation of the stress axis with respect to the slip system will change $\cos \phi_N \cos \phi_D$.

→ Although τ_{CRSS} and σ_y are material prop. Both cannot be constant.

NPTEL ETSC, IIT DELHI

Let us look at that now essentially what we saw that the resolved shear stress is given in terms of the applied tensile stress times, a geometrical factor $\cos \phi_N \cos \phi_D$. Now, when σ when the stress applied tensile stress reaches yield stress σ_y , the resolved shear stress reaches its critical value critical resolved shear stress $\cos \phi_N \cos \phi_D$.

Now yield stress appears to be a material property. So, does the critical resolved shear stress at what stress so critical resolved shear stress can be thought of as a microscopic yield stress macroscopically we are applying a tensile stress and at a critical value of tensile stress yielding happens. Similarly microscopically on the slip plane in the slip direction we are applying resolved shear stress which reaches its critical value, critical resolved shear stress at the point of yielding.

Now, if we look at this relationship this particular factor which we call the Schmid factor, this depends upon ϕ_N , note what is ϕ_N ϕ_N is the angle between stress axis and slip plane normal. And ϕ_D is the angle between stress axis and slip direction. So, this factor depends on the orientation of a stress axis from the orientation with respect to the slip system.

So, if I change my orientation if I change the orientation of the stress axis this factor will change, a change in orientation of the stress axis with respect to the slip system that is the slip direction and the slip plane will change the Schmid factor..

Then what will happen what will happen to this equality if both CRSS and σ_y are constant then by changing $\cos \phi$ and $\cos \phi_D$ I cannot maintain this equality, but the equality has to be maintained at the point of yielding. So, this means since $\cos \phi$ and $\cos \phi_D$ can be independently varied by choosing my stress axis both CRSS, and σ_y cannot be constant.

Although they are material property, but they cannot both be constant, both cannot be constant. So, the question now is which of these is constant which remains constant and which vary is a important question.

(Refer Slide Time: 06:04)

Q: If we change $\cos \phi$ and $\cos \phi_D$ by changing the orientation of stress axis wrt the slip system what happens to maintain the equality

$$\tau_{CRSS} = \sigma_y \cos \phi \cos \phi_D$$

X i) τ_{CRSS} changes, σ_y remains constant
 ✓ ii) σ_y " , τ_{CRSS} remains constant
 X iii) Both σ_y and τ_{CRSS} change.

Schmid performed Experiment to establish which option is correct.

ETSC, IIT DELHI

So, the question if we change $\cos \phi$ and $\cos \phi_D$ by changing the orientation of stress axis with respect to the slip system what happens slip system what happens to maintain the equality τ_{CRSS} is equal to $\sigma_y \cos \phi$ and $\cos \phi_D$.

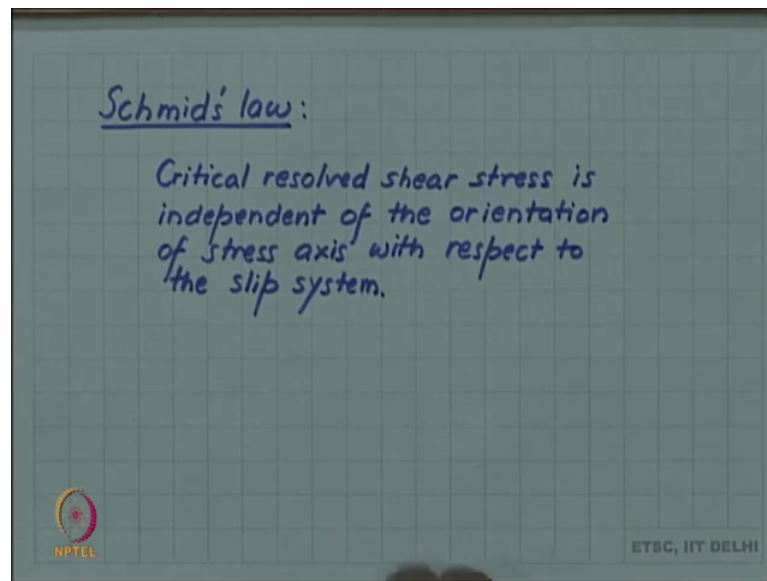

So, let us write down the options τ_{CRSS} changes σ_y remains constant the other option can be σ_y changes τ_{CRSS} remains constant or there can be a third option that both σ_y and τ_{CRSS} change which of these options is right.

Again we are this is also similar to the question which we had raised regarding the crystal structure change that these questions cannot just be answered by thinking logically or philosophically. These questions are question of science and question should be put finally, to the nature that is we have to do proper experiments to establish what is

happening and these experiments the person who did the experiment was Schmid Schmid performed experiments.

So, one has to perform very careful experiments to establish which option is correct and his experiments indicated that actually it is the option 2 which is right. The experiments showed that critical resolved shear stress remains constant whereas, σ_y changes so this is what is called Schmid's law. So, let us write it as a law Schmid's law.

(Refer Slide Time: 11:08)

So, essentially the content of the Schmid's law is that the critical resolved shear stress; shear stress is independent of the orientation of a stress axis with respect to the slip system.

As you change your stress axis with respect to the slip system $\cos \phi$ and $\cos \phi D$ changes, but critical resolved shear stress will not change, quite often this actually quite often mistakenly this relationship itself is taken as Schmid's law.

But note that this relationship is only relating the yield stress to the critical resolved shear stress this does not tell that critical resolved shear stress will remain constant or yield stress will remain constant if you change $\cos \phi$ and $\cos \phi D$ that was Schmid's contribution, Schmid perform careful beautiful experiment to establish this and that is why we honor him by naming this law after him. So, critical resolved shear stress is independent of the orientation of a stress axis with respect to the slip system.

(Refer Slide Time: 13:45)

ANISOTROPY OF YIELD STRESS

$$\tau_{CRSS} = \sigma_y \cos \phi_N \cos \phi_D$$
$$\sigma_y = \frac{\tau_{CRSS}}{\cos \phi_N \cos \phi_D}$$

← constant by Schmid's law

Yield stress of a single crystal depends upon the orientation of the stress axis.

NPTEL ETSC, IIT DELHI

So, a consequence of this is obvious that the yield stress becomes an isotropic because recall the relationship we had τ_{CRSS} is equal to $\sigma_y \cos \phi_N \cos \phi_D$. Now if I change the orientation of the stress axis $\cos \phi_N$ and $\cos \phi_D$ will change if τ_{CRSS} remains constant by Schmid's law then σ_y has to change.

So, we can write this as $\sigma_y = \tau_{CRSS} / (\cos \phi_N \cos \phi_D)$. So, yield stress of single crystal this is constant by Schmid's law. The yield stress of a single crystal depends upon orientation of the stress axis or in other word yield stress is an isotropic. Because $\cos \phi_N$ and $\cos \phi_D$ will depend upon the orientation of the stress axis.
