**Fick's second law**

(Refer Slide Time: 00:05)

So, we are looking at diffusion and we discussed the Fick's first law of diffusion, which was relating flux to the concentration flux to the concentration gradient. We now we will look at Fick's second law which second law can be easily derived on the basis of mass conservation. So, let us look at what is Fick's second law. So, let us consider a block.

(Refer Slide Time: 00:38)

And let us assume that there is a concentration gradient which is existing in this block. So, concentration of some diffusing species is high at one end and is low at the other end and it is gradually decreasing. And let us plot that concentration gradient as a function of distance along the bar. And let us say that concentration profile is something like this, this is the concentration as a function of  $x$  and this is the distance  $x$ .

I am deliberately drawing not a straight line, but a curve because I want to have different slopes at different locations of  $x$ . So, let us assume that at some location  $x$ , let us say that this is a location  $x$  and let us look at another nearby location  $x$  plus  $\Delta x$ . So, I am considering what is going to happen in this volume of width  $\Delta x$  let us say that the cross-sectional area cross sectional area is  $A$ .

So, we have a volume  $A \Delta x$ , we have a volume  $\Delta v$  which is  $A \Delta x$ . Now if we apply we have we already know our Fick's first law. So, if we apply the Fick's first law we see that at the  $x$  we have a certain concentration gradient. And at  $x$  plus  $\Delta x$  we have another concentration gradient. So, based on this concentration gradient there will be a flux, there is a flux of these species. So, there will be a flux at  $x$ . Let me call that  $j_x$  which will be transporting material into this volume.

And then at  $x$  plus  $\Delta x$  we have another slope so we will have another flux, which will now be transporting the material outside this volume and I am calling that  $j_{x+\Delta x}$  because that is at a location  $x$  plus  $\Delta x$ .

So, in a small we want to find out what changes happen in the concentration in this volume  $\Delta v$  as a function of time. So, in time  $\Delta t$  how much does the concentration of this volume changes. So, look let us look at that concentration change in this volume. So, mass entering  $\Delta v$  at  $x$  in time interval  $\Delta t$ . So, let us call that mass  $m_x$  and what will that mass be. So, let us recall the definition of this flux  $j_x$  plus flux is mass per unit area per unit time.

So, if we take the flux  $j_x$  and if we multiply it with the area so, it is over the cross-sectional area  $A$  and if we multiply it with the time interval  $\Delta t$  we will know the total amount of mass which is entering in this time interval into this volume  $\Delta v$  at the cross-section  $x$ .

Similarly, if we now write mass leaving  $\Delta v$  at  $x + \Delta x$  in the same time interval then we have  $m_{x+\Delta x}$  only the value of  $j$  is changing the cross-sectional area is the same and the time interval is the same. So, if we take the difference of these 2 we will find what is the mass accumulating in this volume. So, let us do that so mass accumulating in  $\Delta v$  in time  $\Delta t$ . So, this mass let us call that  $\Delta m$  is nothing but mass in and mass out minus mass out. So, this is  $j_x A \Delta t$  minus  $j_{x+\Delta x} A \Delta t$ .

So, we can write this as  $(j_x - j_{x+\Delta x}) A \Delta t$ .

(Refer Slide Time: 09:53)

Mass accumulating in  $\Delta v$  in time  $\Delta t$

$$\begin{aligned} \Delta m &= (j_x - j_{x+\Delta x}) A \Delta t \\ &= -(j_{x+\Delta x} - j_x) A \Delta t \\ &= -\Delta j A \Delta t \end{aligned}$$

Concentration change in  $\Delta v$  in time  $\Delta t$

$$\begin{aligned} \Delta c &= \frac{\Delta m}{\Delta v} \\ &= \frac{-\Delta j A \Delta t}{A \Delta x} \\ &= -\frac{\Delta j}{\Delta x} \Delta t \end{aligned}$$

$\rightarrow \frac{\Delta c}{\Delta t} = -\frac{\Delta j}{\Delta x}$

NPTEL ETSC, IIT DELHI

So, we have mass accumulating in volume  $\Delta v$  in time interval  $\Delta t$   $\Delta m$  equal to  $j_x \Delta x - j_{x+\Delta x} \Delta x + A \Delta t$ , we just rewrite it as  $j_x \Delta x - j_{x+\Delta x} \Delta x + A \Delta t$ , we are rewriting like this because this expression in the bracket now is the difference that what we will call  $\Delta j$ . So, this is the difference  $\Delta j A \Delta t$ . So, this is the mass which has accumulated in the volume in time interval  $\Delta t$ . So, we want to find out the concentration change in time  $t$ .

So, the concentration change let us look at the concentration change now. So, concentration change or change in concentration in  $\Delta v$  in time  $t$ , now remember that in Fick's law we are using the concentration as volumetric concentration. So, by very definition the concentration change  $\Delta c$  a mass divided by volume so the  $\Delta m$  by  $\Delta v$ ,  $\Delta m$  is the change in mass and  $\Delta v$  is the volume of the element which we are considering and if we write this as  $\Delta j A \Delta t$  and  $\Delta v$  is nothing but  $A \Delta x$ .

So,  $A$  cancels from numerator and denominator and we can write this now as  $\Delta j$  by  $\Delta x \Delta t$  and if we transpose  $\Delta t$  on this side we can find the rate of change of concentration. So, we can write this as  $\Delta c$  by  $\Delta t$  is equal to  $-\Delta j$  by  $\Delta x$ .

So, this is a nice equation we have arrived at which is giving me that average rate of change of concentration in the time interval  $\Delta t$  is the rate of change of flux with the  $x$  coordinate. So, the spatial rate of change of flux is being linked to the temporal rate of change of concentration. So, we already have arrived at our equation only these are the average values and we want to convert it into a differential equation. So, all we have to do now is to take the limit.

(Refer Slide Time: 13:55)

The image shows a handwritten derivation on a grid background. At the top, it states:  $\lim_{\Delta t \rightarrow 0} \left( \frac{\Delta c}{\Delta t} \right) = - \lim_{\Delta x \rightarrow 0} \left( \frac{\Delta j}{\Delta x} \right)$ . Below this, it says  $\Rightarrow \frac{\partial c}{\partial t} = - \frac{\partial j}{\partial x}$  and labels it as "Fick's 2nd. Law 1st form." The next line reads: "We can obtain another form of Fick's 2nd. Law by replacing j using Fick's 1st. Law". This is followed by the equation  $j = -D \frac{\partial c}{\partial x}$ . Then, it shows the substitution:  $\Rightarrow \frac{\partial c}{\partial t} = - \frac{\partial}{\partial x} \left( -D \frac{\partial c}{\partial x} \right)$ . This simplifies to  $= D \frac{\partial^2 c}{\partial x^2}$  with the note "Assuming D is independent of x". Finally, it presents the boxed equation  $\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2}$  and labels it as "Fick's 2nd. Law 2nd. Form.". At the bottom left is the NPTEL logo and the text "The DIFFUSION EQUATION in mathematics." and at the bottom right is "ETSC, IIT DELHI".

So, if we take the limit of delta t tending to 0 of del c by del t. So, instead of average over the time interval we will now have the instantaneous rate of change of concentration and similarly on the other side we take the limit delta x tending to 0.

So, instead of average change over a finite distance delta x we will have the rate of change at a particular position in a space. So, this quickly then changes this process of taking the limit will then change it into the differential equation we now have del c by del t is equal to minus del j by del x. So, this is one of the forms of Fick's second law. So, it is it is saying that rate of change of concentration with time is the negative rate of change of flux with space. So, this is one form of Fick's second law let us write it Fick's second law first form.

Another form of the equation can be found simply by replacing j using Fick's first law. So, we can obtain another form another form of second law by replacing j using Fick's first law. And remember that in the Fick's first law we had established that j is equal to minus D del c by del x. So, if we do that we find del c by del t equal to minus del by del x minus D del c by del x.

So, and if we now assume that D is constant independent of x we can take it out of the differential. So, we will get this as D del 2 c by del x square. So, we have another form del c by del t is equal to D del 2 c by del x square Fick's second law, Fick's second law second form and this of course, is assuming D to be constant. Assuming D in

independent of  $x$ , so, essentially Fick's second law is a differential equation and it is a very famous and important differential equation in mathematics and it is because it comes in diffusion problem this equation itself is known as the diffusion equation.

So, this is the diffusion equation mathematics that is if any variable any variable  $c$  it need not be concentration if any variables  $c$  if it is differential coefficient with respect to time is related to it is second differential coefficient with respect to space through a constant like this mathematically is called a diffusion equation.

And we have seen that we arrive at this simply by the mass balance or all that was done is to see how much is coming into the volume and how much is leaving and the difference is what is getting accumulated and that is what get converted into a concentration change. We will look at a kind of solution of this equation in the next video.
