**Power law creep in MMC's,  $n > 7$**

- Using a back extrapolation technique it is possible to determine the threshold stress value

Ref: Li & Langdon, Scripta Mater 1997

So till the last portion we were talking about Power law creep and we were looking at the Power law creep behavior of metal matrix composites where one might get a stress exponent value larger than 7 and what we said was this larger than 7 value of  $n$  is actually due to the presence of a threshold stress.

So if you invoke a threshold stress into your deformation equation then after that you would see that the stress exponent value would come in the range of 4 to 7 which we normally associate with Power law creep. So that was about metal matrix composites.

And we also said how by using a simple back extrapolation technique, it is possible to find out the magnitude of the threshold stress and like I said, I am going to give you an example on how to determine the threshold stress for a material, for metal matrix composites, this is something that I will cover in the coming portion.

Now talking of stress exponent values greater than 7,

(Refer Slide Time: 01:13)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

typically when you see  $n$  value greater than 7, then the mechanism of creep is, or the regime in which the creep deformation is happening is known as Power law breakdown.

So Power

(Refer Slide Time: 01:25)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

law breakdown is the creep regime where you will see very high stress exponent values and generally these are greater than 7.

So what has been observed in the Power law breakdown regime or basically the characteristic of the Power law breakdown regime is that the slope of the curve between strain rate and

stress continues to increase with stress and is no longer constant with changes in stress at higher stress.

So basically what the statement means is, so if you have epsilon dot versus sigma in the power law creep regime, so you will have n is equal to 4 to 7 or let us say in this case, let us take an example of n is equal to 5.

(Refer Slide Time: 02:00)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The n values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in n.
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

So here n is equal to 5, this value does not change irrespective of the increase in stress. So you have stress increasing but the slope continues to remain constant at n is equal to 5.

But

(Refer Slide Time: 02:14)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

in Power law breakdown regime when you have epsilon dot versus sigma, so what you have is, you have something like that so the slope continues to change and with increase in stress. So as the stress increases if you will see the slope is increasing

(Refer Slide Time: 02:30)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

as stress is increasing. So that is the characteristic of Power law breakdown.

So if you get your creep data and if you plot the minimum creep rate, that is the secondary stage creep rate against the applied stress and if you see something like that where the slope seems to change as a function of stress then that means you are most probably in the Power law breakdown regime.

And in addition to  $n$  so which is increasing what people have also observed is, within the Power law breakdown regime generally the activation energy of deformation is also observed to decrease with an increase in  $n$ . So what it basically means is, as your  $n$  increases there is concomitant decrease in the activation energy of deformation.

So  $Q$  seems to decrease as  $n$  increases. Now if you

(Refer Slide Time: 03:24)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_L$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

$Q \downarrow$  as  $n \uparrow$

notice we are saying  $n$  increases when stress increases.

(Refer Slide Time: 03:28)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_L$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

$Q \downarrow$  as  $n \uparrow$   
 $n \uparrow$   $\sigma \uparrow$

So this also means that  $Q$  seems to decrease when stress, applied stress is higher. And that is the behavior of Power law breakdown

(Refer Slide Time: 03:37)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_L$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

$Q \downarrow \sigma \uparrow$   
 $n \uparrow \sigma \uparrow$   
 $Q \downarrow \sigma \uparrow$  PLB

regime.

So the activation energy of deformation also seems to come down in the Power law breakdown regime. Now generally we look at activation energy of deformation as either equal to lattice self-diffusion, so you have  $Q$  is equal to  $Q_L$ , or which is basically the lattice diffusion activation energy.

Or you could have  $Q$  is equal to  $Q_{gb}$  which is activation energy helped by the presence of the grain boundaries which is grain boundary diffusion activation energy.

In addition to that we also talked about viscous glide creep mechanisms where the activation energy of diffusion was dependent on the solute diffusivity. So we said  $Q$  is probably or  $Q$  is equal to  $Q_s$  which depends upon how fast the solutes diffuse along with the dislocations.

Now in Power law breakdown while some people have noticed that the activation energy of deformation is close to that of lattice diffusion, but by and large people claim that the activation energy of diffusion in this material

(Refer Slide Time: 04:39)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

$Q \downarrow$  as  $n \uparrow$   
 $n \uparrow \sigma \uparrow$   
 $Q \downarrow \sigma \uparrow$  PLB

is in the range of  $Q$  is equal to  $Q_p$  where  $Q_p$  is defined as the activation energy

(Refer Slide Time: 04:46)

### Power law breakdown (PLB), $n > 7$

- The slope of the curve between strain rate and stress increases with stress and is no longer constant with changes in stress at higher stress. The  $n$  values are higher than 7.
- Within PLB, generally the activation energy of deformation is generally observed to decrease with an increase in  $n$ .
- Although some have found  $Q = Q_d$ , by and large  $Q = Q_p$  where  $Q_p$  is activation energy for pipe diffusion is what is agreed upon.

$Q_p =$   
 $Q \downarrow$  as  $n \uparrow$   
 $n \uparrow \sigma \uparrow$   
 $Q \downarrow \sigma \uparrow$  PLB

for pipe diffusion.

So this is what people have agreed upon. So pipe diffusion we will talk about this, so people say that in the Power law breakdown regime the activation energy for deformation is equal to that required, is equal to that of pipe diffusion.

(Refer Slide Time: 05:03)

## Power law breakdown (PLB)

- In some cases, the activation energy was found to be equal to the activation energy for pipe diffusion suggesting that the mechanism of deformation could be dislocation climb but facilitated by short circuit diffusion of vacancies through the large number of dislocation cores generated at high applied stresses.
- Sherby and Burke suggest that vacancy diffusion due to vacancy supersaturation at high applied stresses can be associated with the rate controlling mechanism.
- The breaking down of subgrain walls and cross-slip or cutting of forest dislocations instead of dislocation climb has also been proposed as the rate controlling mechanism.
- Generally PLB remains poorly understood and this is due to the relatively small number of studies that have been carried out in this creep regime.
- Ref: G. M. Pharr, "Some observations on the relation between dislocation substructure and power law breakdown in creep," *Scripta Metall.*, 15 (1981) 713-717.

as long as the dislocation line stretches, so you have a vacant space below that dislocation, so what people are saying is there is short circuit of diffusion of vacancies, so the vacancies find it easy to diffuse through a large number of dislocation cores and the number of dislocations increase as we increase the applied stress.

So as we increase the applied stress, the density of dislocation increases so vacancies find easier paths for traveling through the dislocation core. That is why the activation energy is going to come down as

(Refer Slide Time: 06:30)

### Power law breakdown (PLB)

Power law breakdown regime one could say that vacancy supersaturation and vacancy diffusion due to vacancy supersaturation at high applied stresses can be the rate controlling mechanism.

Another mechanism that people have suggested is the breaking down of sub grain walls

(Refer Slide Time: 07:23)

### Power law breakdown (PLB)

- In some cases, the activation energy was found to be equal to the activation energy for pipe diffusion suggesting that the mechanism of deformation could be dislocation climb but facilitated by short circuit diffusion of vacancies through the large number of dislocation cores generated at high applied stresses.
- Sherby and Burke suggest that vacancy diffusion due to vacancy supersaturation at high applied stresses can be associated with the rate controlling mechanism.
- The breaking down of subgrain walls and cross-slip or cutting of forest dislocations instead of dislocation climb has also been proposed as the rate controlling mechanism.
- Generally PLB remains poorly understood and this is due to the relatively small number of studies that have been carried out in this creep regime.
- Ref. G. M. Pharr, "Some observations on the relation between dislocation substructure and power law breakdown in creep," *Scripta Metall.*, 15 (1981) 713-717.
- Ref. J. P. Poirier, "Is power law creep diffusion controlled?" *Acta Metall.*, 26 (1978) 629-637.
- Ref. O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

and cross-slip or cutting of forest dislocations. So other mechanisms that people have suggested is you could have sub grain walls breaking down.

So in Power law creep we are talking of the formation of sub grains within the material so, so one mechanism that has been proposed is that these walls tend to break down in the Power law creep regime.

(Refer Slide Time: 07:44)

### Power law breakdown (PLB)

- In some cases, the activation energy was found to be equal to the activation energy for pipe diffusion suggesting that the mechanism of deformation could be dislocation climb but facilitated by short circuit diffusion of vacancies through the large number of dislocation cores generated at high applied stresses.
- Sherby and Burke suggest that vacancy diffusion due to vacancy supersaturation at high applied stresses can be associated with the rate controlling mechanism.

- Generally PLB remains poorly understood and this is due to the relatively small number of studies that have been carried out in this creep regime.
- Ref: G. M. Pharr, "Some observations on the relation between dislocation substructure and power law breakdown in creep," *Scripta Metall.*, 15 (1981) 713-717.
- Ref: J. P. Poirier, "Is power law creep diffusion controlled?" *Acta Metall.*, 26 (1978) 629-637.
- Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

And another mechanism that has been proposed is cross-slip of forest dislocation. So since we are going to have a large number of dislocations and in the presence of high stresses these dislocations move, there can be a significant of, amount of cross-slip or cutting of forest dislocations happening and this could also be the rate controlling mechanism

(Refer Slide Time: 08:05)

### Power law breakdown (PLB)

- In some cases, the activation energy was found to be equal to the activation energy for pipe diffusion suggesting that the mechanism of deformation could be dislocation climb but facilitated by short circuit diffusion of vacancies through the large number of dislocation cores generated at high applied stresses.
- Sherby and Burke suggest that vacancy diffusion due to vacancy supersaturation at high applied stresses can be associated with the rate controlling mechanism.

- Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

in Power law creep regime.

However having said this that people have said dislocation climb could be one of the rate controlling mechanisms, people said diffusion of vacancies through dislocation cores leading to  $Q$  is equal to  $Q_p$  could be the rate controlling mechanism and in some other cases people have said the breaking down of sub grain walls and cross-slip or cutting of forest dislocations is the rate controlling mechanism.

However by and large you can say the mechanism of Power law breakdown regime is poorly understood and this is due to the relatively small number of studies that have been carried out in this creep regime. So in a way, still there is some amount of work that can be carried out to understand what exactly is the mechanism of deformation in the Power law breakdown regime.

(Refer Slide Time: 08:56)

### Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right)$$

Now one thing that people have noticed is Power law breakdown generally occurs at high stresses, something that I already mentioned. So you go from epsilon dot, you have say  $n$  is equal to 5 and when you go to higher stresses

(Refer Slide Time: 09:11)

## Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right)$$

you see something like that so basically

(Refer Slide Time: 09:14)

## Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right)$$

the Power law breakdown is the result of high applied stresses.

And what people have noticed is if the stress is normalized with elastic modulus then typically Power law breakdown is observed around  $\sigma/E$  is equal to 10 to the power minus 3.

(Refer Slide Time: 09:34)

## Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right)$$

In that range is where Power law breakdown has been observed. In other cases people have said Power law breakdown also corresponds to strain rates greater than  $10$  to the power minus  $9 D$ .

So if  $D$  is the diffusivity people have also noticed

(Refer Slide Time: 09:54)

## Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right)$$

that if the creep deformation is proceeding at strain rates greater than  $10$  to the power minus  $9 D$ , then also one could say that Power law, Power law breakdown creep regime could ensue.

Now in this high stress and high strain rate regime, in Power law breakdown regime creep rates vary with stress through an exponential function. So the governing equation of

(Refer Slide Time: 10:24)

## Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right)$$

creep in the Power law breakdown regime is described here. So you see an exponential dependence on the applied stress.

So while this regime is observed in all details and therefore the underlying mechanism of creep like I mentioned earlier is not well-understood, but one thing is clear. The strain rate

(Refer Slide Time: 10:46)

## Power law breakdown (PLB)

- Power-law breakdown (PLB) occurs at relatively high stresses equal to or greater than around  $10^{-3}E$  ( $E$  is modulus of elasticity); this has also been correlated with strain-rates at or greater than  $10^{-9}D$  ( $D$  is diffusivity).

Ref: O.D. Sherby and P.M. Burke, "Mechanical Behavior of Crystalline Solids at Elevated Temperatures," *Progress in Mater. Sci.*, 13 (1968) pp. 325-390.

- In this high stress and high strain-rate regime, the creep-rates vary with stress through an exponential function. While this region is observed in all materials under appropriate conditions, the underlying mechanism of PLB is still not well understood.

$$\dot{\epsilon} = A \exp\left(\frac{-Q_c}{kT}\right) \exp\left(\frac{B\sigma}{kT}\right) \quad \dot{\epsilon} \propto \exp\left(\frac{B\sigma}{kT}\right)$$

of deformation is dependent, has an exponential dependence on the applied stress. So that is the equation of Power law breakdown.

(Refer Slide Time: 10:55)

## Power law breakdown (PLB)

- Power law breakdown has been suggested to be similar to that of deformation in a normal tension test. This is on account of the high strain rates of deformation
- Hence the microstructure in a material creeping in the PLB regime is expected to be similar to that observed in a material following regular tension test

Now on account of the fact that you need high stresses for this deformation to happen, Power law breakdown has also been suggested to be similar to that of deformation that the material experiences in a normal tension test. So if you are carrying out a normal tension test, typically the strain rates of deformation are of the range of  $10$  to the power minus  $4$  or  $10$  to the power minus  $3$ .

And in Power law breakdown similar range of strain rates are observed. So people have come to conclude that Power law breakdown could also be considered like that of a normal tension test.

Now in account, on account of that, so since you are calling that Power law breakdown could be like a normal tension test then what also could be said is that the type of microstructure that the material would develop after deforming in the Power law breakdown regime should be similar to that of a material deforming in a regular tension test.

So the strain rates of deformation are similar. So the microstructure that one would generate in a tension test following plastic deformation in a tension test, a similar type of microstructure is expected to form in a material that has deformed by creep in the Power law breakdown regime.

(Refer Slide Time: 12:11)

### Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

So the kind of microstructure that people have observed is shown in this slide. So this is a microstructure taken from sodium chloride single crystals which were deformed in the Power law breakdown regime.

So what has been noticed by the researchers is that the samples showed a high amount of dislocations. So the samples following the creep in P L B regime had high dislocation density and dislocation cell structures, so these are dislocation cell structures that would form

(Refer Slide Time: 12:49)

### Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

during creep in the Power law breakdown regime.

So that is the kind of microstructure. If you observe something like that after you creep test, then you can, a kind of sure that your material is certainly not in the Power law creep regime but it could be, it is most probably in the Power law breakdown regime. So that is what is happening.

So,

(Refer Slide Time: 13:18)

### Transitions in deformation mechanisms

Ok, so that brings me to the end of the different types of mechanisms that people have observed during creep of materials.

So we talked about these various mechanisms, we talked about  $n$  is equal to 1 as Newtonian viscous creep mechanisms, where under which you had Nabarro-Herring, you had Coble, you had Harper-Dorn.

Then we talked

(Refer Slide Time: 13:45)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

$n=1$  Newtonian viscous creep  
N-H, Coble,  
H-D

about  $n$  is equal to 2 we said it is grain boundary sliding where you could have

(Refer Slide Time: 13:53)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

$n=1$  Newtonian viscous creep  
N-H, Coble,  
H-D

$n=2$  Grain Boundary sliding

offsets, the sliding of the grains leads to offsets in fiducial markers, then you had  $n$  is equal to 3, we said it is viscous glide controlled creep

And then we said

(Refer Slide Time: 14:08)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

- $n=1$  Newtonian viscous creep  
N-H, Coble, H-D
- $n=2$  Grain Boundary Sliding
- $n=3$  Viscous glide controlled creep

$n$  is equal to 4 to 7, it is Power law where it could be either Weertman's model or it could be the Jogged screw model

(Refer Slide Time: 14:20)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

- $n=1$  Newtonian viscous creep  
N-H, Coble, H-D
- $n=2$  Grain Boundary Sliding
- $n=3$  Viscous glide controlled creep
- $n=4-7$  Power law Weertman's model / J-S

and then we said of  $n$  greater than 7 which is the Power law breakdown regime.

(Refer Slide Time: 14:26)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

- $n=1$  Newtonian viscous creep  
N-H, Coble, H-D
- $n=2$  Grain Boundary Sliding
- $n=3$  Viscous glide controlled creep
- $n=4-7$  Power law Weertman's model/J-S
- $n > 7$  PLB

And what is interesting is one can go from this  $n$  is equal to 1 regime to  $n$  greater than 7 by increasing stress. So if you increase the stress or another way of saying is if you increase the  $\sigma$  by  $E$

(Refer Slide Time: 14:44)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

- $n=1$  Newtonian viscous creep  
N-H, Coble, H-D
  - $n=2$  Grain Boundary Sliding
  - $n=3$  Viscous glide controlled creep
  - $n=4-7$  Power law Weertman's model/J-S
  - $n > 7$  PLB
- $\sigma/E$
- ↓

value which is the normalized stress value, higher the normalized stress value greater is the probability that you will be either, the material will creep either in the  $n$  is equal to 4 to 7 regime or  $n$  greater than 7 regime.

Of course when we say higher  $\sigma$  by  $E$ , we are also assuming that

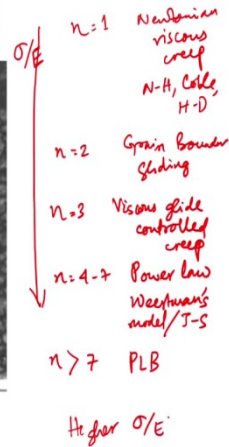

(Refer Slide Time: 15:01)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

the grain, the microstructure is also favorable for that particular deformation mechanism to operate because we know microstructures such as grain size also has a significant role to play

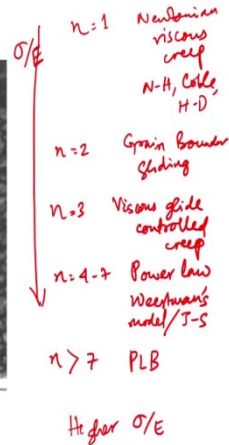

(Refer Slide Time: 15:11)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

d

in determining the rate controlling mechanism of deformation.

But ignoring the effect of microstructure, if you generally talk of sigma by E, what people have noticed is, as you increase the sigma by E value, you go from one mechanism of creep, so basically you transit from one mechanism of creep to another

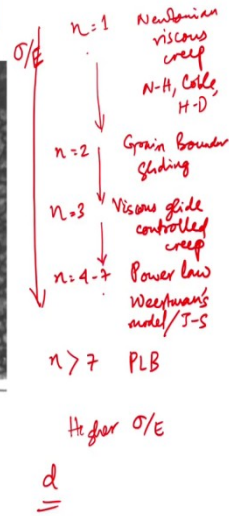

(Refer Slide Time: 15:29)

## Power law breakdown (PLB)

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

and so around sigma by E greater than 10 to the power minus 3,

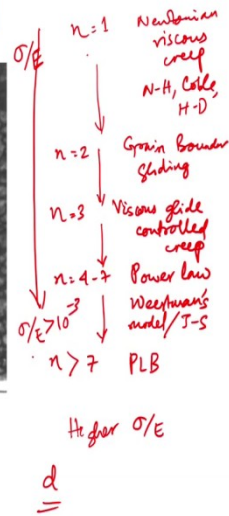

(Refer Slide Time: 15:35)

## Power law breakdown (PLB)

- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

you are basically

(Refer Slide Time: 15:36)

## Power law breakdown (PLB)

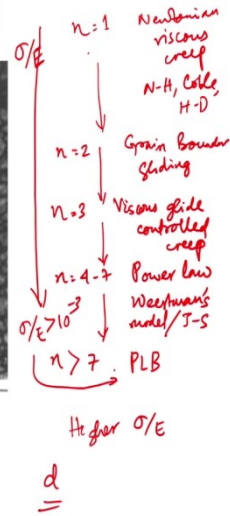

- Samples show high dislocation density and dislocation cell structures could form
- Dislocations structures in NaCl following creep deformation in the power law breakdown regime

S. V. Raj and G M Pharr, "Creep substructure formation in sodium chloride single crystals in the power law and exponential creep regimes," *Mater. Sci. Engg. A*, 122 (1989) 233-242.

in the P L B regime.

So basically the point is creep mechanism, the deformation mechanisms can undergo transitions. So basically you can see change in the deformation behavior as a function of applied stress, temperature and grain size.
