NPTEL ONLINE CERTIFICATION COURSE

Health, Safety & Environmental Management in Offshore and Petroleum engineering (HSE)

Module 3:

Environmental issues and Management

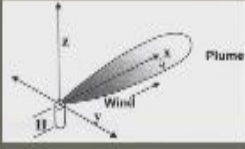

Lecture 6: Dispersion release models for gas

Dear friends welcome to the 6th lecture on module three there we are focusing environmental issues and management in this lecture we are going to discuss about dispersion release models which are applicable to gaseous releases this is lecture under module three in the course of HSE in offshore and petroleum engineering at NPTEL IIT Madras.

(Refer Slide Time: 00:41)

Dispersion models for neutrally and positively buoyancy gas

- Plume and Puff models are commonly used to model the vapor cloud dispersion
- Plume model describes continuous emission of materials at height, H above the ground level
- Wind blowing direction is taken along X axis
- Coordinate system is shown in the figure

NPTEL - IIT Madras

There are various dispersion models available in the literature which we are seen in the earlier lectures or chemical releases now let us talk about various dispersions models the playing one pluck models which are useful for neutrally and positively buoyant gases the plume of puff

models are commonly used to model the vapor cloud dispersion which we are see in detail in the last lectures also the plume model describes the continuous emission of materials of height H above the ground level.

The wind blowing direction is generally taken along the X-axis and the coordinate system for evaluation or estimating the dispersion model for a plume release is given in the figure here where along the wind blow direction will always see X is taken along the wind direction Y is taken normal to the wind direction and Z is measured along the altitude of height of the building so the entire cloud dispersion which is form but dispersion of the gas from the specific source which can be a stack of a building is actually a plume model which can be estimated from the equations which will given to you in the next slide onward.

(Refer Slide Time: 02:00)

Plume dispersion model

Average gas concentration is given by:

$$C(x, y, z) = \frac{Q}{2H\sigma_y\sigma_zU} \exp\left[-\frac{1}{2}\left(\frac{y}{\sigma_y}\right)^2\right] \times \left\{ \exp\left[-\frac{1}{2}\left(\frac{z-H}{\sigma_z}\right)^2\right] + \exp\left[-\frac{1}{2}\left(\frac{z+H}{\sigma_z}\right)^2\right] \right\}$$

Where, C(x,y,z) is the average concentration (kg/m³), H is height of the releasing source (m), (x,y,z) are distances from the source in downwind, cross wind and vertical direction respectively (m), Q is the release strength (kg/s) U is wind velocity (m/s)

σ_y, σ_z

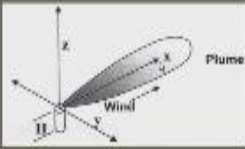

NPTFI - IIT Madras

Then the plume release models or dispersion model gives you average gas concentration from equation available in the screen now by in this equation C function of xy and z where xy and z.

(Refer Slide Time: 02:19)

Dispersion models for neutrally and positively buoyancy gas

- Plume and Puff models are commonly used to model the vapor cloud dispersion
- Plume model describes continuous emission of materials at height, H above the ground level
- Wind blowing direction is taken along X axis
- Coordinate system is shown in the figure

 © NPTL - IIT Madras 2

Or measure respectively along the wind direction normal to the wind direction and along the altitude of the height of the building respectively.

(Refer Slide Time: 02:29)

Plume dispersion model

Average gas concentration is given by:

$$C(x, y, z) = \frac{Q}{2H\sigma_y\sigma_zU} \exp\left[-\frac{1}{2}\left(\frac{y}{\sigma_y}\right)^2\right] \times \left\{ \exp\left[-\frac{1}{2}\left(\frac{z-H}{\sigma_z}\right)^2\right] + \exp\left[-\frac{1}{2}\left(\frac{z+H}{\sigma_z}\right)^2\right] \right\}$$

Where, $C(x,y,z)$ is the average concentration (kg/m^3), H is height of the releasing source (m), (x,y,z) are distances from the source in downwind, cross wind and vertical direction respectively (m), Q is the release strength (kg/s), U is wind velocity (m/s)

σ_y, σ_z are dispersion coefficients in Y and Z directions

© NPTEL - IIT Madras

So see x, y, z is actually the average concentration of the gas released using the plume dispersion model which is given in the units of Kg/m^3 . In this equation what you see is the height of the releasing source which is given in meters. x, y, z are nothing but the distances from the source in the downwind, cross wind and vertical directions respectively, all of them in meters because you have multiplied as here Q is the release strength which is kg/s which is the release strength of the gas of the specific concentration and you use in this equation is nothing but the wind velocity in m/s .

Whereas the σ_x, σ_y use in this equation in terms of σ_y and z, x, y and z are the dispersion coefficients in the x, y and z direction respectively.

(Refer Slide Time: 03:34)

Plume dispersion model

- Case 1: ground level centerline concentration ($y=z=0$)
$$C(x,0,0) = \frac{Q}{2H\sigma_y\sigma_zU} \exp\left[-\frac{1}{2}\left(\frac{H}{\sigma_z}\right)^2\right]$$
- Case 2: Ground, centerline, release height, $H=0$
$$C(x,0,0) = \frac{Q}{2H\sigma_y\sigma_zU}$$
- In both the cases, X is implicit in the dispersion coefficients

The plume release model can be calculated as different cases arise for example let us take case 1 where the ground level center line concentration can be given by this equation the moment is a ground level I would always associate $z = 0$ I am talking about a specific point of release concentration therefore y is also 0 when I said in this equation y and z is 0 I will get $c(x)$ which can be given by this equation case 2 can be ground center line and release height but of course h is taken as 0 in this case.

So I can always find out the ground center line release of the plume model by given this equation as the concentration of the gas release in both the case of the some equation X you can see is implicit is in dispersion coefficients automatically.

(Refer Slide Time: 04:25)

Maximum plume concentration

- It always occurs at the release point
- For releases above ground, maximum concentration occurs downwind along the centerline (X axis)
- Distance at which maximum ground level concentration would occur is given by:
$$\sigma_z = \frac{H}{\sqrt{2}}$$
- Maximum concentration is estimated by:
$$C_{max} = \frac{2Q}{\sigma_y \sigma_z U} \left(\frac{\sigma_z}{H} \right)$$

NPTEL - IIT Madras

5

In σ_y and σ_z respectively now a question comes what to be the value of maximum plume concentration maximum plume concentration always occurs at the release point the release point can be tip of the stack of any chimney or any tower which is dispersing gas into the environment for releases above ground the maximum concentration occurs in the downward wind direction along the center line which is taken as x axis for the whole calculation the distance at which maximum ground level concentration.

Would occur is given by a relationship I just see from here the maximum concentration see max is estimated by your relationship as you see here whereas σ_z and σ_y are the dispersion coefficients available along z axis and y axis respectively.

(Refer Slide Time: 05:21)

Puff dispersion model

- ④ It describes instantaneous release of material
 - Example: sudden release of chemical from a ruptured vessel
 - Consequence: large vapor cloud is dispersed from the rupture point
- ⑤ Puff model is used to describe a plume
 - For example, effect of change of wind direction is a dynamic model of plumes
- ⑥ Average concentration for puff release is given by:

$$C(x, y, z) = \frac{Q \exp(-z/H)}{(2\pi)^{3/2} \sigma_x \sigma_y \sigma_z} \exp\left[-\frac{1}{2}\left(\frac{x-ux}{\sigma_x}\right)^2\right] \times \exp\left[-\frac{1}{2}\left(\frac{y}{\sigma_y}\right)^2\right] + \left\{ \exp\left[-\frac{1}{2}\left(\frac{z-H}{\sigma_z}\right)^2\right] + \exp\left[-\frac{1}{2}\left(\frac{z+H}{\sigma_z}\right)^2\right] \right\}$$

© NPTEL- IIT Madras

Alternatively for instant time is release we can also look at puff dispersion models for continuous release you have already seen plume dispersion models for instantaneous release one looks for a puff dispersion model this describes instantaneous release of material example could be a sudden release of chemical from a rupture vessel consequences can be large vapor cloud is dispersed from the rupture point puff model is use to describe a plume alternatively for a example effect of change of wind direction.

Is a dynamic model of plumes the average concentration for puff release is given by the equation shown here where c x y z is actually the con concentration at different points of x y z measured respectively as shown in the previous slide so depends upon instantaneous release of energy Q where are the σ_x σ_y and σ_z and of course h x y and z to carry the same conventional meaning as expressed in the last equation.

(Refer Slide Time: 06:28)

Special cases of Puff modeling

- 1. Case 1: Total integrated dose at ground level (i.e. $z=0$) is given by:

$$\text{Dose}(x, y, 0) = \frac{Q_{\text{in}} \tau_{\text{in}}}{H \sigma_x \sigma_y} \exp \left[-\frac{1}{2} \left(\frac{y}{\sigma_y} \right)^2 - \frac{1}{2} \left(\frac{H}{\sigma_z} \right)^2 \right]$$
- 2. Case 2: Concentration on ground below puff center is given by:

$$C(x, 0, 0, t) = \frac{Q_{\text{in}} \tau_{\text{in}}}{\sqrt{2\pi} H^{1/2} \sigma_x \sigma_y} \exp \left[-\frac{1}{2} \left(\frac{H}{\sigma_z} \right)^2 \right]$$
- 3. Case 3: Puff center on ground (i.e. $H=0$) is given by:

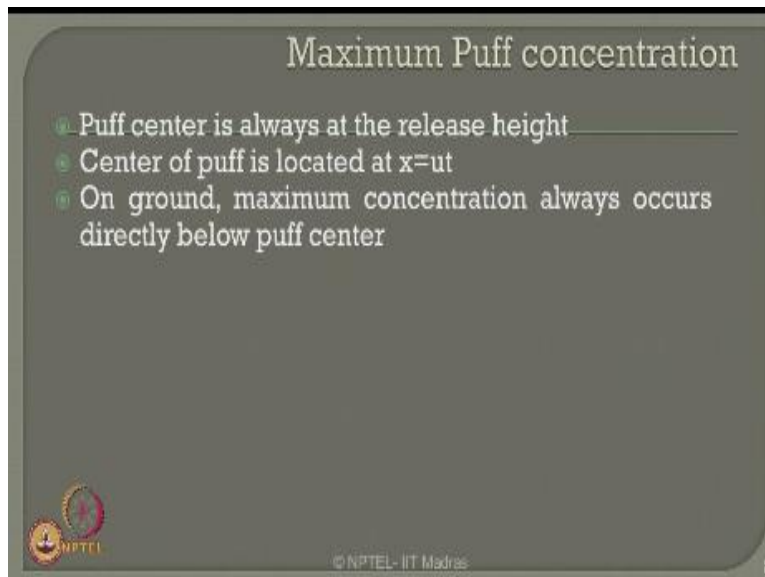

$$C(x, 0, 0, t) = \frac{Q_{\text{in}} \tau_{\text{in}}}{\sqrt{2\pi} H^{1/2} \sigma_x \sigma_y}$$

© NPTEL- IIT Madras 7

There can be some certain specific cases what you called special cases of puff model let say case one the total integrated dose to be obtained a ground level that is where z is 0 is given by a dosage x y where 0 where can taken an energy of instantaneous is releases of the gas given by this expression if one wants to find out the concentration on ground exactly below the puff center then it came a given by this equation as you see here y is also said to 0 in this case if one is interested to find out.

The puff center on the ground where h is given to be 0 then one can find in this case of given equation as you see here in all the questions the σ_z y and x are actually given by the dispersion coefficient concentrations at various access x y z respectively.

(Refer Slide Time: 07:23)

Maximum Puff concentration

- 1 Puff center is always at the release height
- 2 Center of puff is located at $x=ut$
- 3 On ground, maximum concentration always occurs directly below puff center

NPTEL IIT Madras 8

The maximum puff concentration is always at the release height the puff center is taken as release height the center puff is located at $x = ut$ on ground the maximum concentration always occurs directly below the puff center.

(Refer Slide Time: 07:40)

Isopleths

- It measures the cloud boundary at a fixed concentration
- Represents the lines of constant concentration
- Steps to determine isopleths
 - Step 1: Determine concentrations along centerline at fixed points downwind

The diagram shows a horizontal line representing the centerline of a dispersion plume. An arrow labeled 'Wind' points to the right above the line. A vertical tick mark on the left side of the line is labeled 'Release Point'. Several dots are placed along the centerline to the right of the release point, representing fixed points for concentration measurements.

- Step 2: Find off-center distance to isopleth (y) at each point from the following equation

$$y = \sigma_z \sqrt{2 \ln \left(\frac{C(x, 0, 0, t)}{C(x, y, 0, t)} \right)}$$

Where $C(x, 0, 0, t)$ is downwind ground centerline concentration and $C(x, y, 0, t)$ is isopleth concentrations at (x, y)

© NPTEL- IIT Madras 9

Friends there is a concept in dispersion release models what to call as Isopleths, Isopleths measure the cloud boundary at fixed concentration Isopleths actually a represent lines of constant concentration there are different steps available in the literature to compute or to plot Isopleths step number 1 determine the concentrations along the center line and fixed point in the down wind direction as you see here is may be in progressive direction this becomes a center a line of my dispersion model.

Is a release point keep on plotting or finding out concentration at different points along the fixed line which is in the progressive direction of downwind word no at these points we know the concentrations available step number 2 find the option that distance to Isopleths which is given by y at each point from the following equation for example in each point I want to find the half center distance to Isopleths which is given by this equation where in this equation see x 0 0 T is a downwind ground center line concentration what to get from this particular point. And see x y 0 t is an Isoplethe concentration at a specific value of x and y respectively.

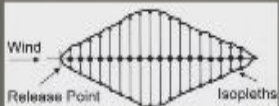

(Refer Slide Time: 09:07)

Isopleths

- Step 3: Plot isopleth offset for both directions at each point

- Step 4: Connect the points

10

In step number 3 I plot the Isopleths because I know the opposite of the concentration in different points now I plot the Isopleths opposites for both the directions at each point then I connect the opposite points as you see here and I draw Isopleths.

(Refer Slide Time: 09:24)

Dispersion coefficients- estimate

- ① Dispersion coefficients are important to estimate the plume and puff models
- ② They depend on stability class and downwind distances
- ③ Following are steps to estimate the dispersion coefficients
 - Step 1: Identify Pasquel stability class by using meteorological data such as wind speed, heat radiation, cloud cover etc

Surface wind speed	Day, incoming solar radiation			Night, Cloud cover thickly overcast		Anytime Heavy overcast
	Strong	Moderate	Slight	> 1/2 Low clouds	< 3/8 clouds	
<2 m/s	*A	A-B	B	F	F ₁	D
2-3 m/s	A-B	B	C	E	F	D
3-5 m/s	B	B-C	D	D	E	D
5-8 m/s	C	C-D	D	D	D	D
> 8 m/s	C	D	D	D	D	D

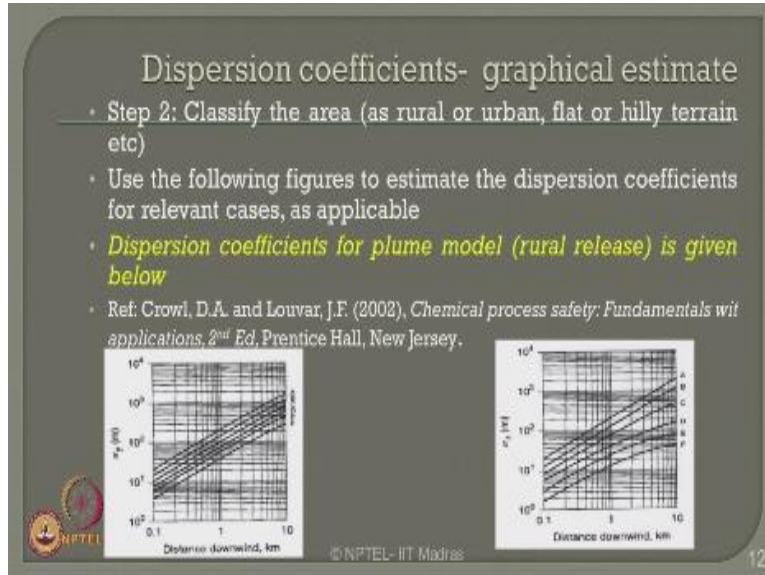

One major issue which is generally focused in estimate of release models is the dispersion coefficient σ_x σ_y and σ_z respectively which are very vital to estimate the gas release concentration do it instantaneous model or be the continuous study state release models the dispersion coefficients are important to estimate the plume puff model releases they actually depend on stability class and downwind distances following are some of the steps to estimate the dispersion coefficients.

One can identify the Pascal stability class by using meteorological data such as wind speed heat radiation and cloud cover etc. Now you can see here for the surface winds speed varying from 2m/s to more than 6m/s I have the Pascal stability class varying from A to that of F where they are normal cluttered as ABCDF depends upon what could be the dispersion coefficient for different day incoming solar radiation and night cloud cover or alternatively at any time during the heavy overcast.

So I divide the stability class into different normal cluster not only depending upon the surface wind speed but also depending upon whether it is day or night further it is subdivided to slight

moderate and strong incoming solar radiation where as for the night cloud cover can be taken as either more than 50% the low clouds or less than 38 of the cloud formation.

(Refer Slide Time: 11:06)

So for different Pascal stability class I can estimate the dispersion coefficients graphically using this figures seen here a step number 2 classified area find out whether it is a rural urban or hilly terrain use the following figures to estimate dispersion coefficients for relevant cases as applicable dispersion coefficients for plume release model for a rural sector is given below to the reference to crowl and lower in 2002 this is actually a log, log plot which talks about x axis a downward distance in kilometers.

And y axis as gone to dispersion release coefficients σ_y and σ_z respectively so for different Pascal stability class varying from ABCDF in both the cases you will see that if you know the downward wind distance whether you want to calculate if you know the stability class project that a stability class and get the dispersion coefficient respectively on the other hand in this case as well if you know the downward distance vary want to calculate the stability class where you want to calculate dispersion coefficient.

Who stability class is known for you then depending upon the downward distance in kilometer draw a vertical line intersect that line to the respective stability class lines and projective it horizontally to get back a dispersion coefficient maybe σ_y or σ_z respectively which need to use them in the release models in the equation shown in the few slides earlier.

(Refer Slide Time: 12:49)

Similarly one can also determine the dispersion coefficients using graphical estimates for plume release models for advent release centers the earlier figure was given for rural release is for urban release again in this case you got Pascal stability class plotted we will always the see the Pascal stability class in more or the cases remains linear in a log, log plot but of course in all the cases earlier as well as in this case both rural and urban you will see the values for the stability class A and B or much higher compared that are the value for triple class E and F respectively.

(Refer Slide Time: 13:31)

Dispersion coefficients- estimate

- Dispersion coefficients are important to estimate the plume and puff models
- They depend on stability class and downwind distances
- Following are steps to estimate the dispersion coefficients
 - Step 1: Identify Pasquel stability class by using meteorological data such as wind speed, heat radiation, cloud cover etc

Surface wind speed	Day, incoming solar radiation			Night, Cloud cover thickly overcast		Anytime Heavy overcast
	Strong	Moderate	Slight	>1/2 Low clouds	<3/8 clouds	
<2 m/s	*A	A-B	B	F	F	D
2-3 m/s	A-B	B	C	E	F	D
3-5 m/s	B	B-C	D	D	E	D
5-8 m/s	C	C-D	D	D	D	D
> 8 m/s	C	D	D	D	D	D

© 1997 TEL-IT-INDIA

Where Ab refers to AB refers to the wind speed surface wind speed as low as 2m/s are varying from 2 to 3m/s whereas E and F have a marginal variation which can vary from 2 to 5m/s and so on and so forth.

(Refer Slide Time: 13:52)

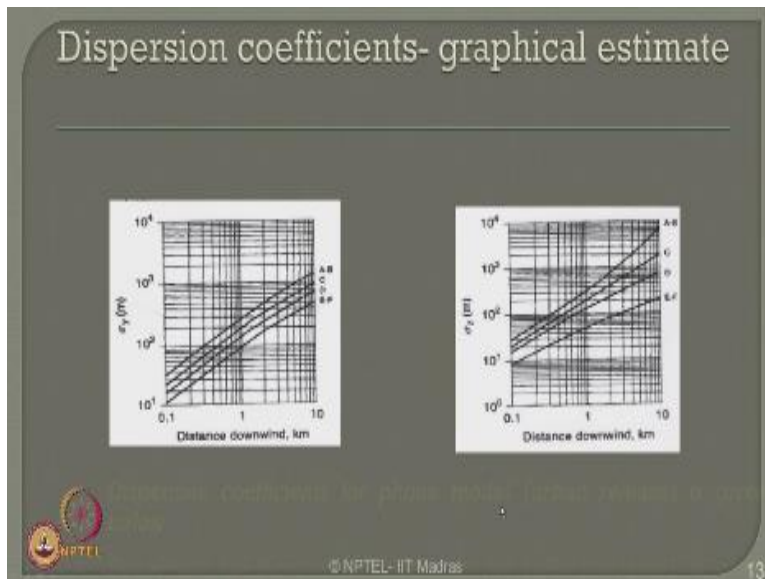

Dispersion coefficients- graphical estimate

- Step 2: Classify the area (as rural or urban, flat or hilly terrain etc)
- Use the following figures to estimate the dispersion coefficients for relevant cases, as applicable
- *Dispersion coefficients for plume model (rural release) is given below*
- Ref: Crowl, D.A. and Louvar, J.F. (2002), *Chemical process safety: Fundamentals with applications, 2nd Ed.*, Prentice Hall, New Jersey.

© NPTEL-IIT Madras

(Refer Slide Time: 13:53)

(Refer Slide Time: 13:53)

Dispersion coefficients- graphical estimate

- Dispersion coefficients for plume model (urban release) is given below

(Refer Slide Time: 13:54)

One can also estimate the puff dispersion model dispersion coefficients for puff release model from the graphical estimates as you see here again the plot shows x axis as distance downward downwind side in kilometers and the plot is available for all Pascal stability class varying from A to F respectively in this case you will see that σ_x is as same as σ_y because it is a puff release model and σ_x varies along the altitude which is given by h height of the release from the graph.

(Refer Slide Time: 14:31)

Plume dispersion model- Dispersion coefficients from equations

- Dispersion coefficients for Plume model can also be estimated from the following equations
- X is the downwind distance (in m) measured from the release source

Area	Stability Class	σ_y (m)	σ_z (m)
Rural conditions	A	$0.22X (1+0.0001X)^{-0.5}$	$0.20X$
	B	$0.16X (1+0.0001X)^{-0.5}$	$0.12X$
	C	$0.11X (1+0.0001X)^{-0.5}$	$0.08X (1+0.0002X)^{1.1}$
	D	$0.08X (1+0.0001X)^{-0.5}$	$0.06X (1+0.0015X)^{1.1}$
	E	$0.06X (1+0.0001X)^{-0.5}$	$0.03X (1+0.0003X)^{1.1}$
	F	$0.04X (1+0.0001X)^{-0.5}$	$0.016X (1+0.0003X)^{1.2}$
Urban conditions	A-B	$0.32X (1+0.0004X)^{-0.5}$	$0.24X (1+0.0001X)^{1.1}$
	C	$0.22X (1+0.0004X)^{-0.5}$	$0.20X$
	D	$0.16X (1+0.0004X)^{-0.5}$	$0.14X (1+0.0003X)^{1.1}$
	E-F	$0.11X (1+0.0004X)^{-0.5}$	$0.08X (1+0.0015X)^{1.1}$

© NPTEL- IIT Madras 15

Alternatively friends one can also estimate these coefficients from the equations given below for rural and urban conditions respectively for a plume release model can always use these equations if you know stability class if you know the rural are urban (m) condition in use the respective equations or estimating the dispersion coefficients σ_y as σ_z for as in this only variable so got to know is x , where X is a downward distance in meters measured from the point of release of the gaseous model.

(Refer Slide Time: 15:08)

Puff dispersion model- Dispersion coefficients from equations

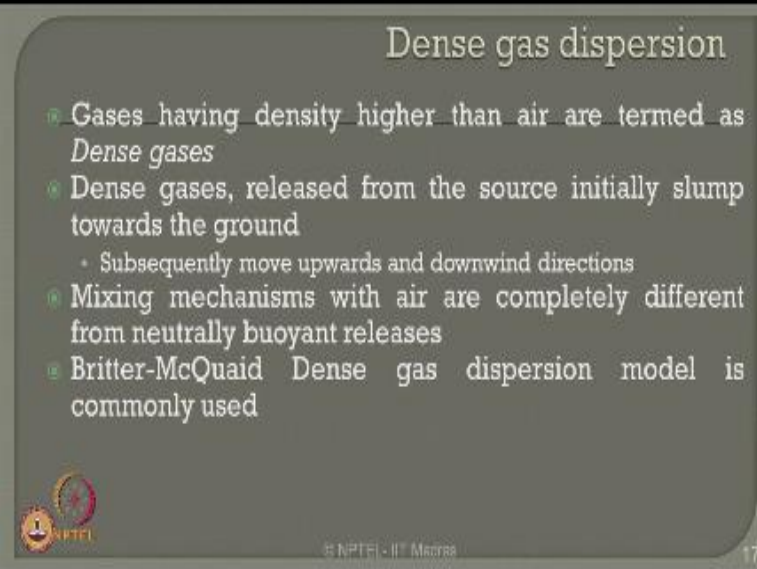

- Dispersion coefficients for Puff model can also be estimated from the following equations
- X is the downwind distance (in m) measured from the release source

Area	Stability Class	σ_x or σ_y (m)	σ_z (m)
Rural conditions	A	$0.18X^{0.92}$	$0.60X^{0.75}$
	B	$0.14X^{0.92}$	$0.53X^{0.73}$
	C	$0.10X^{0.92}$	$0.34X^{0.74}$
	D	$0.06X^{0.92}$	$0.15X^{0.70}$
	E	$0.04X^{0.92}$	$0.10X^{0.66}$
	F	$0.02X^{0.90}$	$0.05X^{0.61}$

© NPTEL - IIT Madras 16

One can also estimate the dispersion coefficients from the equations where puff dispersion model. For puff dispersion model you have the equations given for different stability class varying from A to F for rural conditions whereas the variable here shows either σ_x or σ_y or σ_z for X being the distance measured in meters in the downwind side measured from the release point.

(Refer Slide Time: 15:36)

Dense gas dispersion

- Gases having density higher than air are termed as *Dense gases*
- Dense gases, released from the source initially slump towards the ground
 - Subsequently move upwards and downwind directions
- Mixing mechanisms with air are completely different from neutrally buoyant releases
- Britter-McQuaid Dense gas dispersion model is commonly used

 NPTI

© NPTI - IIT Madras 17

One can also look at the dense gas dispersion relationship. Gases having density higher than air are termed as denser gases. The dense gases released from the source initially slump towards the ground. Subsequently they move upwards and in the windward direction in the downwards side. Mixing mechanisms with air are completely different from neutrally buoyant releases. Britter-McQuaid dense gas dispersion model is commonly used to estimate the consequences and the dispersion release models for this kind of dense gases.

(Refer Slide Time: 16:13)

Britter-McQuiad dense gas dispersion model: steps

- **Step 1: characterize initial buoyancy as given below:**
$$g_0 = g \left(\frac{\rho_0 - \rho_a}{\rho_a} \right)$$
- Where, g is acceleration due to gravity, (ρ_0, ρ_a) are density of the released material and ambient air respectively
- **Step 2: decide release is whether instantaneous or continuous**
$$F = \left(\frac{UR}{x} \right)$$
- Where, u is the wind velocity, x is the distance from the release point and R_d is the duration of the release
- If $F \geq 2.5$, then it is continuous; If $F \leq 0.6$, then instantaneous. For $0.6 < F < 2.5$, use both the approaches and take the maximum

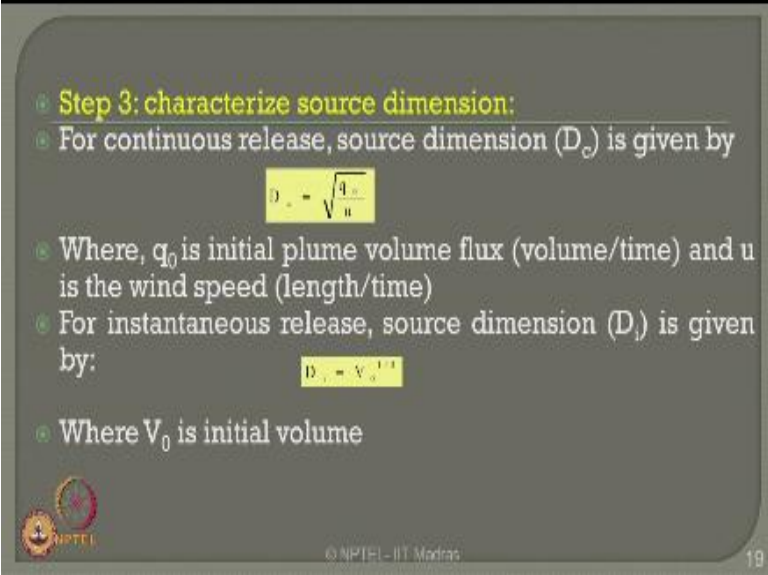

© NPTEL - IIT Madras 18

Britter-McQuiad dense gas dispersion models have different steps to calculate the step number 1, characterize initial buoyancy which can be given by the equation g_0 where g is the acceleration due to gravity in the equation and ρ_0 and ρ_a are density of release models and ambient air respectively. In step number 2, once you know the value of g_0 decide the release whether it is instantaneous or continuous.

In this case u is the wind velocity and x is the distance from the release point where as R_d is called as the duration of release. If the value estimated from the equation 2 here and step number 2 exceeds 2.5 then you treat this as a continuous model which can be taken as a plume model. If the F value comparability to this equation is less than 0.6 then it remains instantaneous which can be used as a puff model.

If the value lies between 0.6 and 2.5 you can use both approaches of plume and puff model and see which ever gives you the maximum value take that for your dispersion release.

(Refer Slide Time: 17:23)

• **Step 3: characterize source dimension:**

- For continuous release, source dimension (D_c) is given by
$$D_c = \sqrt{\frac{q_0}{u}}$$
- Where, q_0 is initial plume volume flux (volume/time) and u is the wind speed (length/time)
- For instantaneous release, source dimension (D_i) is given by:
$$D_i = V_0^{1/3}$$
- Where V_0 is initial volume

 © NPTEL - IIT Madras 19

In step number 3 you calculate the characterization of the source dimension for continuous release which is the plume release model the characteristic source dimension D_c is given by this equation. Where in this equation q_0 is initial plume volume flux which is given in volume per unit time and u is the wind speed in length per time. For instantaneous release models like puff release model the source characteristics dimension D_i is given by this equation. Where V_0 is initial volume to be used in the calculation.

(Refer Slide Time: 17:59)

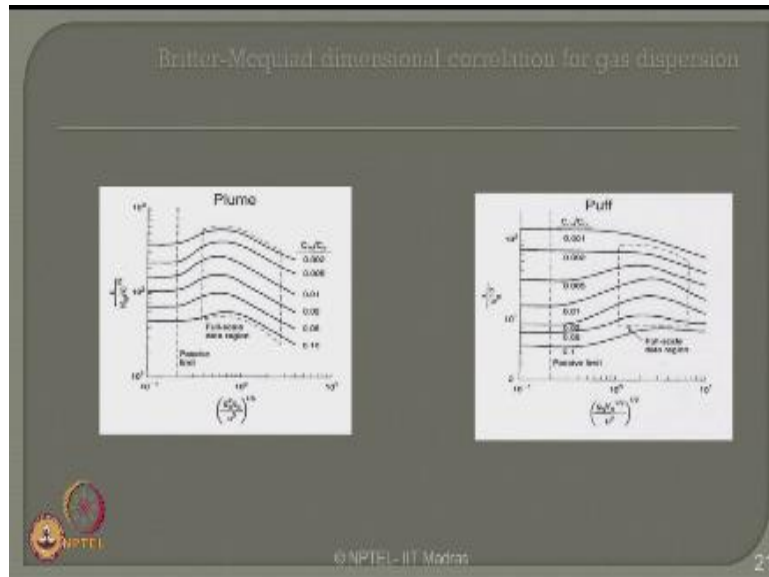

Step 4: Checking criteria:

- For continuous release,
$$\frac{g_0 Q_0}{u^2 D_c} \geq 0.15$$
- For instantaneous release,
$$\frac{\sqrt{g_0 V_0}}{u D_i} \geq 0.20$$

© NPTEL - IIT Madras 20

In the next step can check the criteria you already know the value of g_0 obtain from step number 1. You know D_c or D_a depending up on whether it is continuous release or instantaneous release therefore of a continuous release you try to work out the checking criteria.

(Refer Slide Time: 18:18)

(Refer Slide Time: 18:20)

Step 4: Checking criteria:

- For continuous release,
$$\frac{g_s Q_s}{u^3 D_s} \geq 0.15$$
- For instantaneous release,
$$\frac{\sqrt{g_s V_s}}{u D_s} \geq 0.20$$

© NPTEL - IIT Madras 20

Whether it satisfies the relationship that this equation the value should remain greater than or equal to 0.15 for the model to be remain in the continuous release state. If the value is more than 0.2 for this equation substituted then we can consider this model as an instantaneous release model I can in this case use puff release models. Where as in this case I will use plume release models.

(Refer Slide Time: 18:45)

Now Britter-McQuiad dimension correlation is also available for gas dispersion. If the criteria is then satisfied as given in the previous slide for example.

(Refer Slide Time: 18:58)

Step 4: Checking criteria:

- For continuous release,
$$\left(\frac{g_s \rho_s}{u \cdot D_s} \right) \geq 0.15$$
- For instantaneous release,
$$\frac{\sqrt{g_s \cdot V_s}}{u \cdot D_s} \geq 0.20$$

© NPTEL - IIT Madras 20

In case of instantaneous release this criteria should be satisfied, in the case of continuous release this equation should be satisfied for instantaneous release this equation should be satisfied.

(Refer Slide Time: 19:08)

If this criteria is satisfied then the concentration ratio which we call as C_m/C_0 is given by the following figures. Now for different values of plume and puff models as you see here for different ratios of this constants of $(X/q_0u)^2$ or $g_0^2 q_p u_5$ you try to work out this values in x and y axis and try to know what could be the intersection point and from that point you can always find out what could be the value of the concentration ratio C_m/C_0 whether it is an instantaneous release model or a continuous release model where you can use either a plume release or a puff release respectively.

(Refer Slide Time: 19:50)

➤ If the criterion is satisfied, concentration ratio (C_m/C_0) is also given by the following equations:

Dispersion of dense gas plumes

Concentration ratio (C_m/C_0)	Wind range for	
	$u = 3u_0 \left(\frac{g \Delta \rho}{\rho_0 \Delta T} \right)^{1/3}$	$\beta = 100 \frac{g}{1000 \Delta T}$
0.1	$u \geq 4.75$	1.75
	$-0.23 \leq u < -0.13$	$0.36u + 1.88$
	$0.14 \leq u < 0.2$	$0.30u + 1.78$
0.02	$u \geq 4.08$	1.61
	$-0.68 \leq u < -0.28$	$0.30u + 1.24$
	$-1.78 \leq u < -0.14$	2.40
0.01	$u \geq 3.59$	2.68
	$-0.68 \leq u < -0.30$	$0.45u + 1.70$
	$-0.21 \leq u < -0.15$	2.25
0.005	$u \geq 3.32$	2.25
	$-0.75 \leq u < -0.23$	$0.45u + 2.28$
	$-0.19 \leq u < -0.03$	2.41
0.001	$u \geq 3.02$	2.80
	$-0.67 \leq u < -0.28$	$0.50u + 1.88$
	$-0.22 \leq u < -0.15$	2.61
0.0002	$u \geq 2.69$	2.8
	$-0.69 \leq u < -0.23$	$0.50u + 2.87$

Alternatively one can also compute the concentration ratio C_m/C_0 by the following equations as you see in the slide now.

(Refer Slide Time: 20:00)

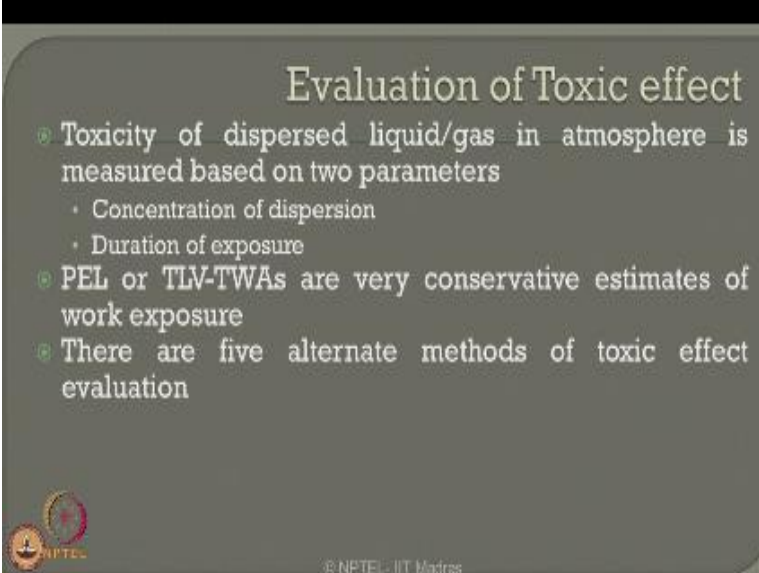

Britter-McQuaid dimensional correlation for gas dispersion

Dispersion of dense gas puffs

CONCENTRATION RATIO (C_m/C_0)	Valid range for $\alpha = \log\left(\frac{H_p V^{0.5}}{g^2}\right)^{1/4}$	$\beta = \log\left(\frac{H_p}{U^{0.5}}\right)$
0.1	$\alpha \leq -0.64$	0.26
	$-0.64 < \alpha \leq -0.47$ $0.43 < \alpha \leq 1$	$0.26\alpha + 0.01$ 0.91
0.02	$\alpha \leq -0.56$	0.85
	$-0.56 < \alpha \leq -0.31$ $0.13 < \alpha \leq 1.0$	$0.26\alpha + 1.16$ $-0.14\alpha + 1.12$
0.01	$\alpha \leq -0.48$	0.89
	$-0.48 < \alpha \leq -0.32$ $0.12 < \alpha \leq 1$	$0.26\alpha + 1.17$ $-0.15\alpha + 1.35$
0.01	$\alpha \leq -0.71$	1.15
	$-0.71 < \alpha \leq -0.29$ $0.27 < \alpha \leq 1$	$0.26\alpha + 1.29$ $-0.34\alpha + 1.66$
0.001	$\alpha \leq -0.52$	1.08
	$-0.52 < \alpha \leq -0.24$ $0.27 < \alpha \leq 1$	$0.26\alpha + 1.03$ $0.26\alpha + 1.35$
0.001	$\alpha \leq 0.27$	1.93
	$0.27 < \alpha \leq 1$	$-0.26\alpha + 1.92$
0.001	$\alpha \leq -0.18$	2.07
	$-0.18 < \alpha \leq 1$	$-0.27\alpha + 2.05$

Similarly one can use the dimension correlation for gas dispersion for the puff model one can find out the concentration ratio C_m/C_0 for the puff release models as you see from the slide now.

(Refer Slide Time: 20:15)

The slide features a dark grey background with a light-colored title and text. The title 'Evaluation of Toxic effect' is centered at the top. Below it, three bullet points are listed. The first bullet point has two sub-bullets. In the bottom left corner, there are two circular logos: one for NPTEL and another for IIT Madras. In the bottom right corner, the text '© NPTEL - IIT Madras' is visible.

Evaluation of Toxic effect

- Toxicity of dispersed liquid/gas in atmosphere is measured based on two parameters
 - Concentration of dispersion
 - Duration of exposure
- PEL or TLV-TWAs are very conservative estimates of work exposure
- There are five alternate methods of toxic effect evaluation

© NPTEL - IIT Madras

One can now estimate evaluation of the toxic effect cost by these kind of release models toxicity of the dispersed liquid or gas in the atmosphere is measured based on two parameters the first parameter is a concentration of the dispersion the second parameter is a duration of the exposure, there are two standards by which one can always check these estimate are remaining within the conservative values you can use either PEL estimates or TLV-TWAs consider to be very conservative estimates for work exposure. There are five alternate methods other then these two to check whether these releases are within the permissible limits for toxic effect valuation.

(Refer Slide Time: 21:28)

The slide is titled "Evaluation of Toxic effect- alternate methods". It lists two methods:

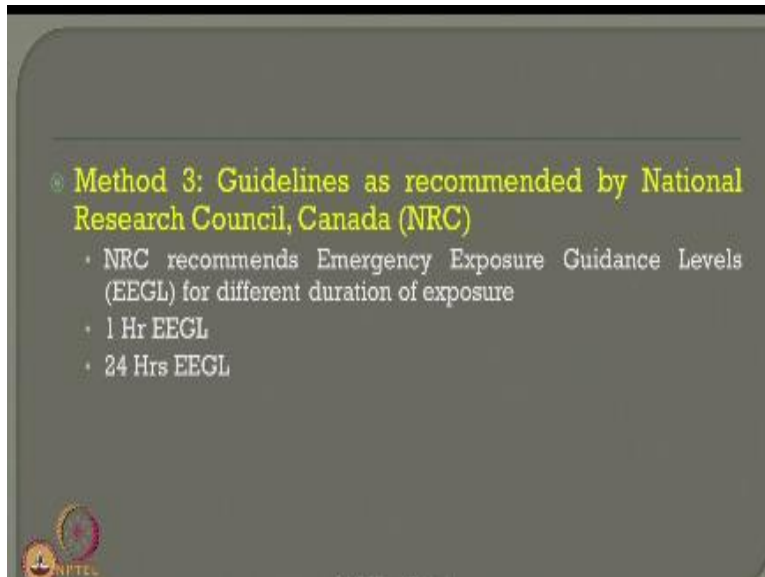

- **Method 1: Based on Emergency Response Planning (ERPG)**
 - This is formulated by American Industrial Hygiene Association
 - ERPG-1, ERPG-2, ERPG-3
- **Method 2: Guidelines as recommended by National Institute for Occupational Safety and Health (NIOSH)**
 - NIOSH recommends standards for Immediately Dangerous to Life and Health (IDLH) that explains the level of acceptable toxicity

At the bottom left, there is a logo for NPTEL. At the bottom center, it says "© NPTEL - IIT Madras". At the bottom right, the number "25" is visible.

Method 1 is based on emergency response planning is ERPG this actually formulated by American industrial hygiene association depending upon the type of gas releases and the chemical release for every release available in the hand book chemical engineering hand book you have what is called ERPG level 1, level 2 and level3 respectively.

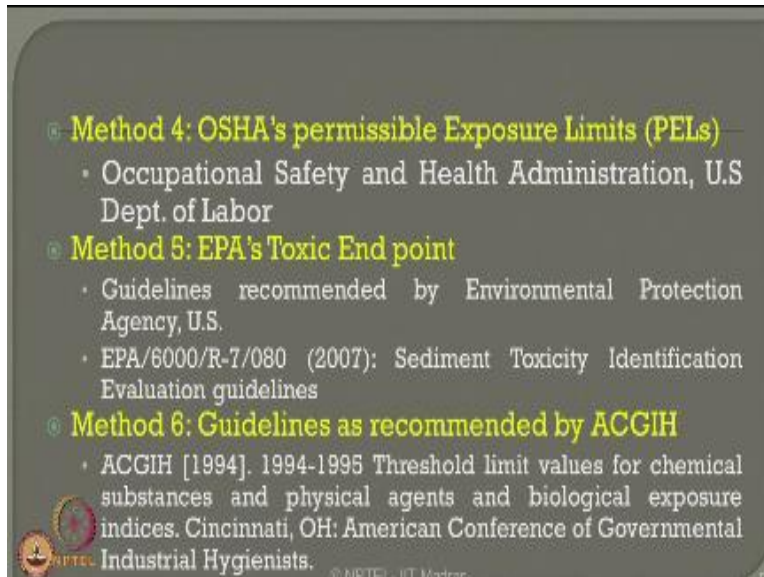

So based on this ERPG guideline available given by AIHA one can always check what is evaluation of the toxic effect on human kind the second method is actually the guidelines proposed by the national institute for occupational safety and health which is NIOSH, NIOSH actually recommends standards for immediately dangerous life and health that explains the level of acceptable toxicity therefore the level of toxicity acceptable to human kind is given by IDLH values alternatively instead of ERPG guide lines as you see in the method 1.

(Refer Slide Time: 22:16)

The third method is actually depending on the guidelines given by the national research council Canada which is NRC, NRC recommends emergency exposure guidance level EEGL for different duration of exposure, varying from one hour EEGL value to the top twenty four hours EEGL value. The next alternate method available to check toxicity permissibility on human mankind is given by method 4.

(Refer Slide Time: 22:43)

Which is OSHA's permissible exposure limit what we called PEL occupational safety and health administration US department of labor recommends permissible exposure limits of different toxic chemical and human kind one can check whether they are within the limits given by PEL of their portion, and one can say whether they safe for the human kind or not the fifth method is actually depending upon the EPAs toxic end point which is based in the guidelines recommended by environmental protection agency EPA of inerte states.

EPA 6000 resolutions 7/80 on 2007 which talks about sediment toxicity identification evaluation guidelines so as a target value for checking the toxicity limits on human mankind. The sixth method is based on the guidelines recommended by American conference of governmental industrial hygiene's which is ACGIH in 1994 ,they give threshold limit values for chemical substances and physical agents of biological exposure indices which is conducted in Cincinnati by the American conference of governmental industrial hygiene's so they give guidelines depending on which one can check whether the toxicity limit of exposure on mankind is within the permissible limits as admissible by the standards.

So friends in this lecture we discussed about different levels of gas releases models for instantaneous and contentious release models which can be a derive relationship for fume and puff models we have seen different equations we have also understood how to compute the dispersion release coefficient and how to find out the dispersion relation C_m/C_0 for different states from the log curves as obtain we also found out what will be different levels of acceptability of toxic limits as given by different standards in international measures thank you very much.
