**Module – 02**  
**Reliability theory and Structural Reliability**  
**Lecture – 12**  
**Failure Domains**

Friends, let us continue with the lecture 12, where we are going to talk about the Failure Domains in system reliability.

(Refer Slide Time: 00:21)

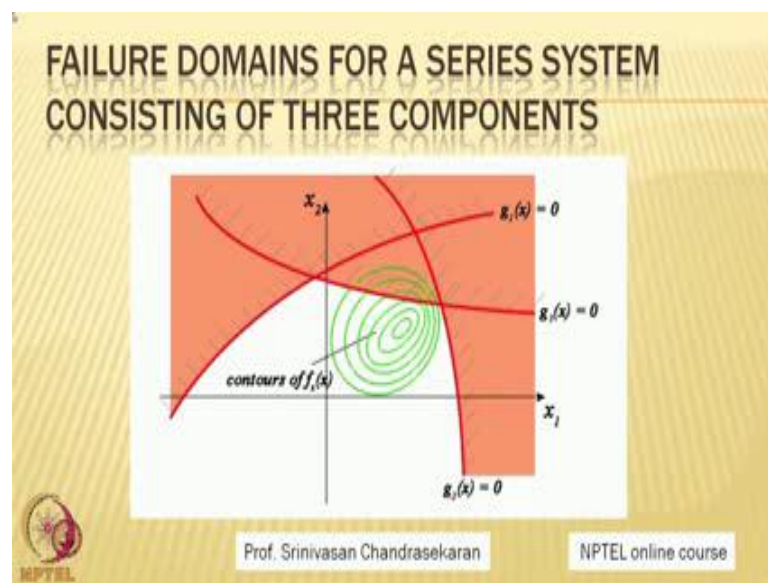

This is lecture in module 2 on system reliability or reliability theory, on the online course risk and reliability of offshore structures. We already said for a series system and a parallel system. I can easily estimate the failure domains. So, let us revise for a parallel system which consists of  $n$  components.  $n$  components the system fails if all its components fail. Therefore, the failure domain is given by as we saw in the last lecture, for a parallel system is actually intersection of the component failure domains  $i$  equals 1 to  $n$ ,  $n$  is the number of components,  $g_i \leq 0$  that is an equation.

Now, let us try to understand the failure domains of series system and parallel system graphically. So, we know that series system failure functions, we know the failure domain of the parallel system. Let us try to understand this graphically. I am of course,

intersection of the failure domains of different sub components other is the union. Because you know the failure condition for series systems is, if any fails the system fails where as for the parallel system see if all of them fail the system fails. Therefore, accordingly we have formulated the failure domain we are given the governing equation, for  $g f x$  as we saw in this lecture and as we understood in the last lecture.

Now, let us try to understand how the limit state function, looks like for a failure domain of series system and that of a parallel system consisting of let us say 3 components let us say  $n$  the number of components is 3. So, in the figure the hatching along the limit surface will be done. So, that it indicates the region in which the corresponding limit state function is lesser than 0. So, kindly pay attention to the figure shown in the screen now.

(Refer Slide Time: 03:25)

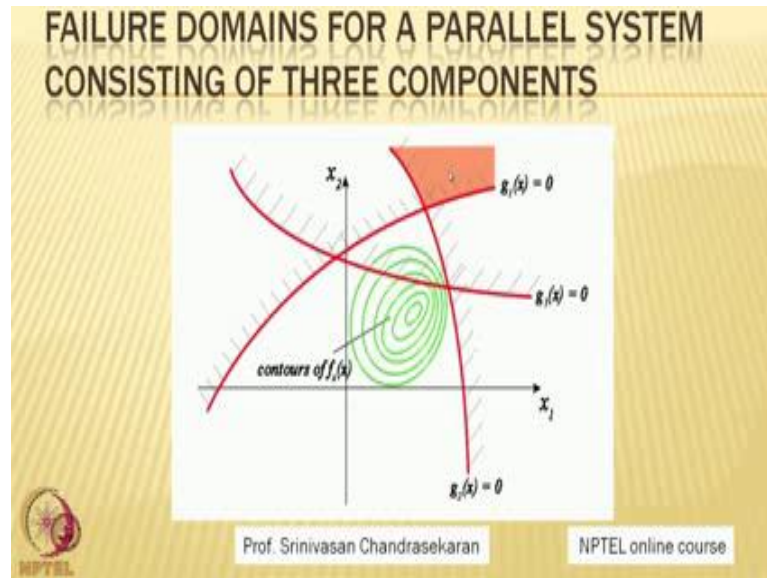

The figure shows the failure domains for a series system consisting of 3 components 1 can see here  $g_1$  of  $x$  is equal to 0. Which indicated by this line the failure domain is this, this area which is the failure domain.

Similarly,  $g_3$  of  $x$  is this line the failure domain is indicated here, and  $g_2$  of  $x$  is this red line the failure domain is indicated here we know for a series system consists of 3 components it is union of all of them. So, the hatched portion actually shows the failure domain of a series system with 3 components;  $x_1$ ,  $x_2$  and  $x_3$  or  $g_1$  of  $x$ ,  $g_2$  of  $x$ ,  $g_3$  of

$x$  being the limit state functions of 3 independent components. Similarly pay attention to the figure shown in the screen now.

(Refer Slide Time: 04:20)

This figure shows the failure domain for parallel system consisting of 3 components and see here  $g_1$  of  $x$  is the limit state function for the first component.  $g_2$  of  $x$  is the limit state function for the second component. The hatched portion shows the failure domain.  $g_3$  of  $x$  is the failure domain for the third component the hatched portion shows the failure domain. Just now as we saw from the equation 1 in the blackboard here the failure domain is an intersection of these failure components. So, the hatched portion becomes the intersection of this failure domain, this failure domain and this failure domain. So, this becomes an intersection of all the 3.

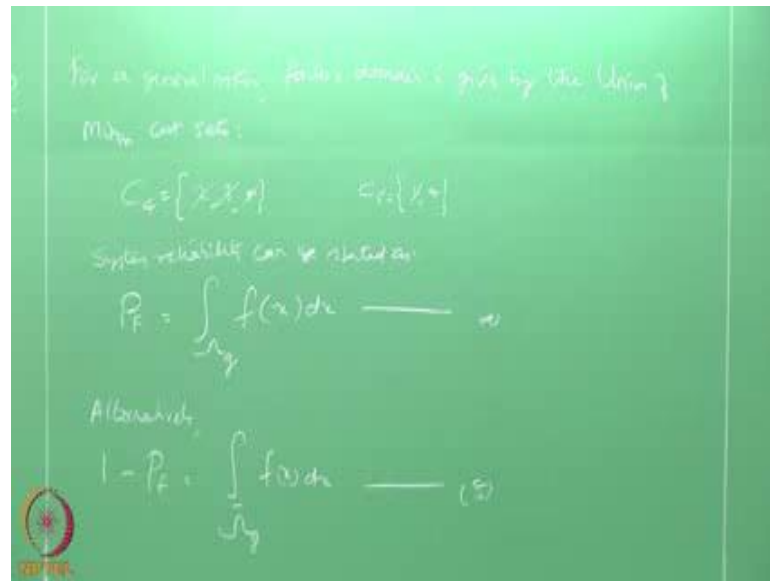

(Refer Slide Time: 05:10)

Therefore for a general system failure domain can be given by cut set formulation that is a failure domain can be written in 2 ways, can be written in 2 ways. Let us use the cut set formulation. For the cut set formulation the failure domain is given by u of m, intersection of i element of c m and failure function is a g i of x less than or equal to 0. Where c m is mth cut set. Now the safe domain for the general system with cut set of representation is define by the path set formulation. So, that is going to be the safe domain which is going to be over i intersection of i element of p i with g of x greater than 0, because I am talking about the safe domain equation number.

Where p i is the ith path set. Now let us try to understand this dialogue or argument with minimum cut sets. So, for a general system failure domain is given by the union of minimum cut sets.

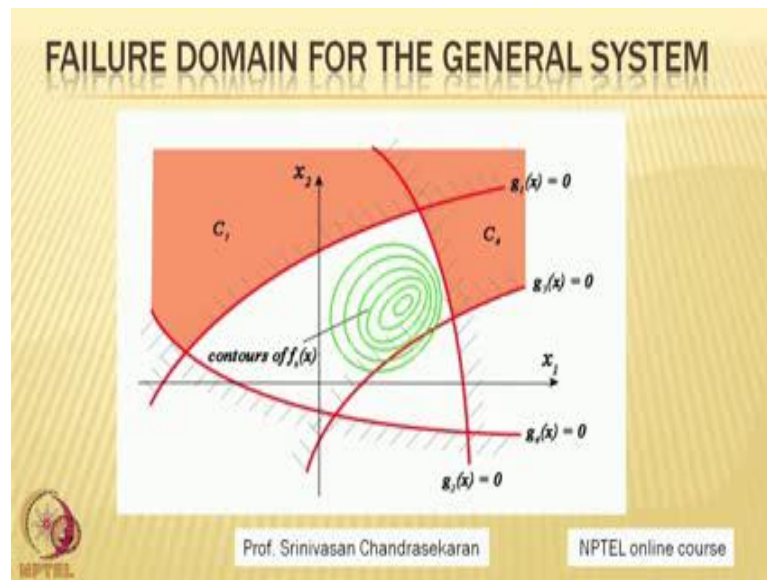

(Refer Slide Time: 07:52)

What are the cut sets in this case for our example 1 is, c 4 which is 2, 3, 4 other is c 5, Which is 1 and 4, these are the minimum cut sets. We have the failure domain was shaded in the figure as we you saw in this screen for some assume component, limit state surfaces.

Therefore, the problem of system reliability now can be stated. Now your failure can be given by  $g$  of  $x$ , which you call as equation number 4. One can always say alternatively probability of failure you can also be given as  $1$  minus probability of failure can be given as integration of  $\bar{g}$  of  $x$ . So, pay attention to the figure shown in the screen now.

(Refer Slide Time: 09:50)

We are now marking the failure domain for the general system, which includes the minimum cut sets  $c_4$  and  $c_5$ . So, one can see here the shaded region, which includes  $c_4$  the failure domains and  $g_1$  of  $x$ ,  $g_2$  of  $x$  or  $g_3$  of  $x$  and  $g_4$  of  $x$  and  $g_2$  of  $x$  or the limit state functions assume for events 1, 2, 3 and 4. So, the shaded region shows the failure domain we can see here;  $g_1$  of  $x$  is got failure domain the surface,  $g_2$  of  $x$  has got a failure domain in this way;  $g_3$  of  $x$  has got a failure domain this way and  $g_4$  of  $x$  has got a failure domain this way. So, the intersection i mean the union of this is going to give me the failure domain of the general system.

Having said this lets us explain the discussion for first order estimates of this way.

(Refer Slide Time: 11:02)

- Prob of union of parallel systems is intersection

for a series system,

$$P_f = P\left(\bigcup_{i=1}^n \{g_i(x) \leq 0\}\right) \quad (6)$$

After applying the appropriate transformation,  
 $u = u(x)$  to the standard normal space,

$$P_F \approx P\left(\bigcup_{i=1}^n \{G_i(u) \leq 0\}\right) \quad (7)$$

Now, in order to compute the system reliability, one must be able to compute the probability of the union of events. For a series system, the probability of failure is given by the probability of the union of events  $g_i(x) \leq 0$ , for  $i = 1$  to  $n$ . This is given by equation number 6. After applying the appropriate transformation  $u = u(x)$  to the standard normal space, the probability of failure is given by equation number 7.

One can find the probability of failure approximately as the probability of the union of events  $G_i(u) \leq 0$ , for  $i = 1$  to  $n$ . When there is an approximation due to mapping of non-normal variables to the standard normal variable space, one has to linearize  $G_i(u)$  at the design point for the  $i$ th limit state function.

(Refer Slide Time: 14:31)

- Limiting  $G_i(u) = 0$  is the design point for the  $i$ th limit state function.  
 -  $G_i(u)$  can be approximated by Taylor Series expansion.  

$$G_i(u) \approx \nabla G_i^T(u_i^*) (u - u_i^*)$$

$$= \left| \nabla G_i(u_i^*) \right| \left[ -\alpha_i^T (u - u_i^*) \right]$$

$$= \left| \nabla G_i(u_i^*) \right| \left[ \beta_i - \alpha_i^T u \right]$$
 (8)

Where,  $u_i^*$  is the design point, reliability index of the  $i$ th component obtained from FORM, applying to the component.

Now, this can be done using Taylor Series Expansion. So, in that case  $g_i$  of  $u$  will be approximately equal to  $g_i^T u_i^* + u_i - u_i^*$ , which is further equal to  $g_i$  of  $u_i^* - \alpha_i^T (u - u_i^*)$ , which can be further written as;  $g_i$  of  $u_i^* - \alpha_i^T u + \alpha_i^T u_i^*$ . It says set of equation as where  $u_i$  and  $\beta_i$  are the design points and reliability index of the  $i$ th component of time from first order reliability methods applying to the component.

The corresponding unit travel vector to limit surfaces.

(Refer Slide Time: 18:21)

The corresponding unit normal vector to the limit state surface  $G_i(u) = 0$  is  $\alpha_i$ .

$$P_i = P\left[ U_{i,1} \left\{ \beta_i - \alpha_i^T u \right\} \leq 0 \right] \quad (9)$$
 By dividing both sides by  $\left| \nabla G_i(u_i^*) \right|$ , we can define  $Z_i$

$$Z_i = -\alpha_i^T W + N(0,1) \quad (10)$$
 where  $W$  is standard normal variable.

$$P_i = P\left( U_{i,1} \left\{ Z_i \leq -\beta_i \right\} \right) \quad (11)$$

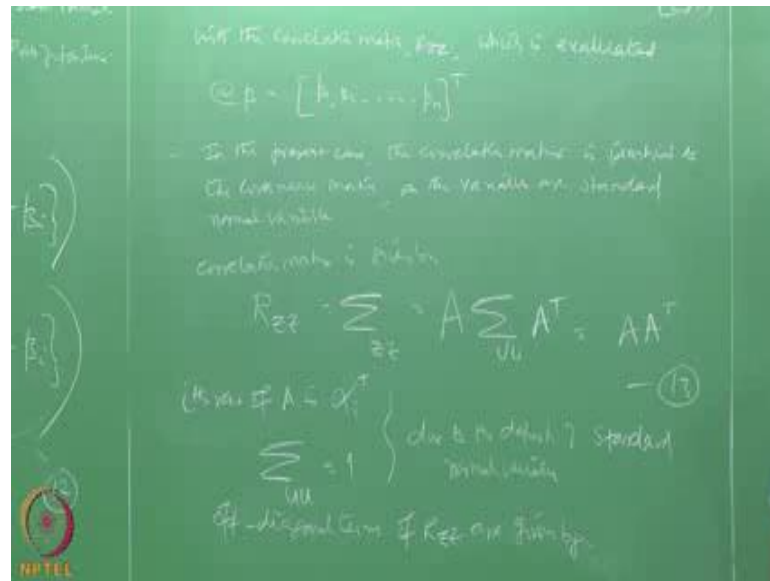

Your surfaces is actually  $g_i$  of  $u$  set to 0 at  $u_i$ . Now, in that case the probability of failure will be approximately equal to probability of intersection, union  $i$  equal 1 to  $n$   $\beta_i$  or  $\beta_i$  minus  $\alpha$  transpose  $u$ . Which is less than or equal to 0 equation number 9. Now dividing both sides of the inequality whether positive scalar, let say my dividing with positive scalar which is  $g_i u_i$  star. One can define as  $z_i$  minus  $\alpha_i$  transpose which is approximately  $n$  of 0, one which is a standard normal variable which 0 mean process in that case probability of failure is given by probability of  $u_i$  equals 1 to  $n$   $z_i$  less than equal to  $\beta_i$ .

(Refer Slide Time: 21:36)

So, with the help of rotational symmetry of the standard normal space which is actually used, when you are transforming the non normal variable to the normal variable, one can use the de Morgan's law. So, in that case to get probability of fail in that case probability of failure is given by probability of  $z_i$  less than,  $\beta_i$  which is equal to 1 minus  $p$  of section of  $i$  equals 1 to  $n$   $z_i$  greater than minus  $\beta_i$ . Which is further equal to 1 minus  $p$  of intersection of  $i$  equals 1 to  $n$   $z_i$  less than or equal to minus  $\beta_i$ , which I call as equation number 12, which can now result to easily because  $i$  have a very interesting argument of normal variability here which can be simply 1 minus  $\beta_i$  and  $r z_i$ .

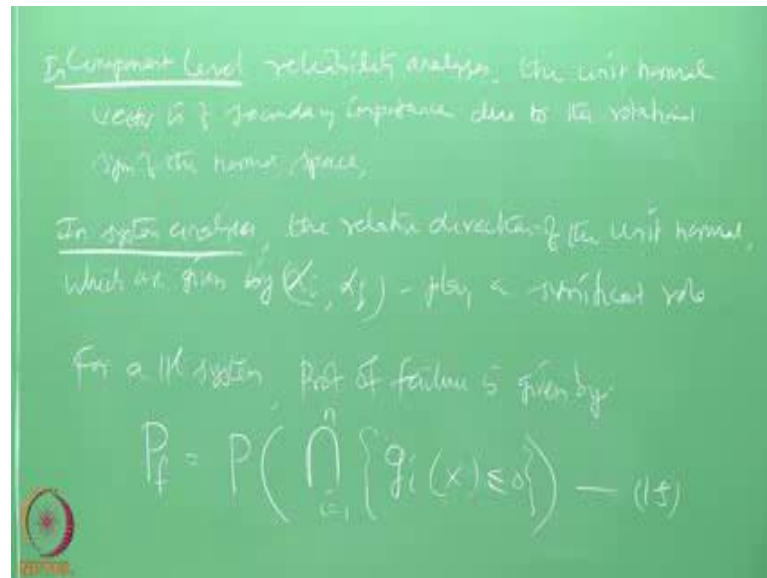

(Refer Slide Time: 23:42)

Where  $\phi_n$  of  $\beta$  is actually the joint normal cumulative distribution function joint normal cumulative density function, CDF with the correlation matrix  $r_z$  which is evaluated at  $\beta$  which is given by different indices  $\beta_1, \beta_2, \beta_n$  transpose in the present case the correlation matrix is identical to covariance matrix. Because of the normal variables in the present case the correlation matrix is identical to the covariance matrix because variables are standard normal. Therefore, the correlation matrix is given by  $r_z z$  is nothing, but which is  $A A^T$ , but a transpose equation 13 the off diagonal terms in this case the  $i$ th row of  $A$  is actually  $\alpha_i$  transpose and actually unity this is due to the definition of the variables.

The off diagonal terms of  $r_z z$  are given by  $z I, z j = \alpha_i^T \alpha_j$  equation number 14 which quantifies the correlation between the failure modes  $i$  and  $j$ .

(Refer Slide Time: 27:04)

So, equation 14 quantifies the correlation between the failure modes  $i$  and  $j$ , now also friends please understand the unlike the reliability analysis component level. So, in component level reliability analysis the unit normal vector is of secondary importance due to the rotation symmetry of the normal space in system analysis you will see there the relative directions of the unit normal places rule which are given by  $\alpha_i$  and  $\alpha_j$ , play a significant role that is a difference actually between the component level and reliability level in analysis.

So, for a parallel system the probability of failure is given by probability of section of  $i$  equals 1 to  $n$   $g_i(x) \leq 0$  - equation number 15.

(Refer Slide Time: 30:32)

$$\begin{aligned}
 &\approx P\left(\bigcap_{i=1}^n \{G_i(u) \leq 0\}\right) \\
 &\approx P\left(\bigcap_{i=1}^n \{(\beta_i - \alpha_i^T u) \leq 0\}\right) \\
 &\approx P\left(\bigcap_{i=1}^n \{z_i \leq -\beta_i\}\right) \quad \text{--- (16)} \\
 &\approx \Phi_{\mathbf{1}, \mathbf{R}}(-\beta, \mathbf{R}^{-1})
 \end{aligned}$$

Now, this can be approximated as follows. So, I say probability of failure is probability of intersection of  $i$  equals 1 to  $n$ , which is  $g_i$  of  $x$  less than or equal to 0. We just approximately equal to probability of intersection of  $i$  equal to 1 to  $n$  of another set of variable which is  $u$  less than 0. Which then can be approximated as probability of intersection of  $i$  equals 1 to  $n$ , which tells me the reliability index  $\beta_i$  minus  $\alpha_i^T u$  into  $u$  variable less than or equal to 0. Which can then be approximated as probability of intersection of  $i$  equals 1 to  $n$ , which is  $z_i$  less than or equal to minus  $\beta_i$  because  $i$  am transforming this into an equivalent normal variable space equation number 16, which will amount to  $\Phi$  of  $n$  of minus  $\beta_i$   $r$   $z$ .

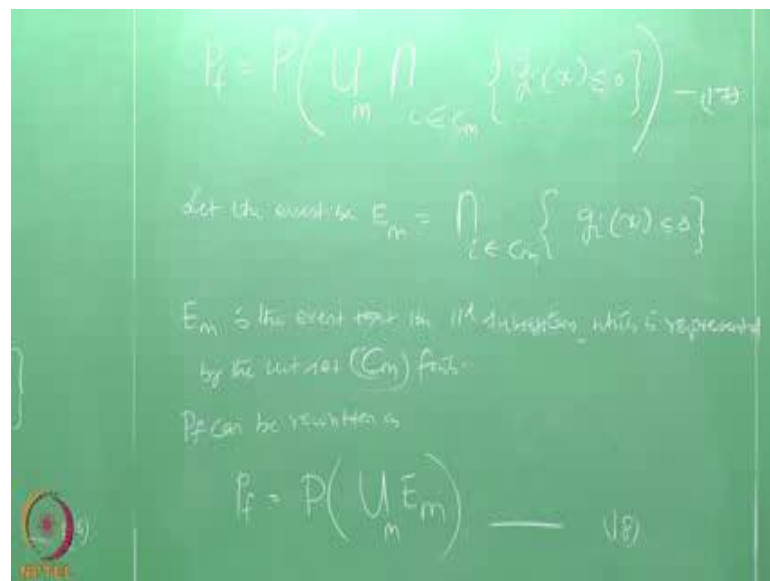

So, we already defined  $\beta$  and  $r$   $z$   $z$  in the previous explanation already said  $\beta$  and  $r$   $z$   $z$  correlation matrix. So, the same definition applies here so, since we are transform the variables from  $x$  to a normal space  $u$   $i$  can apply this algorithm and get my probability of failure is nothing, but the  $\Phi$  function of the 2 variables  $\beta$  and  $r$   $z$   $z$ .

Therefore friends from these 2 lectures, one can easily understand behaviour of a general system can be model either as a parallel system composed of path sets with each path set acting like a sub system of components in series or vice-versa first order approximation for general systems reliability is based on the cut set formulation, which is now discussed a similar approach can also be developed using a path set formulation, which  $i$  live it to you for the self study in order to estimate the probability of failure system using the cut

set formulation 1 need to evaluate the probability of failure of each system. So, let us talk about that.

So, we are trying to estimate the probability of failure general system using cut set formulation. So, 1 need to know the probability of failure of the system which is given by probability of u m section i the element of c m of g i x less than 0 equation 17.

(Refer Slide Time: 33:47)

Now, let the event be  $e_m$  which is intersection of  $i$  element of  $c_m$  which is then extended on the failure domain  $g$  of  $x$  less than 0. Now  $e_m$  is actually the event that the parallel sub system which is represented by the cut set when  $c_m$  fails.

Therefore probability of failure can be now rewritten as probability of  $u_m e$  equation number 18. So, as per the inclusion exclusion of set theory 1 can derive the following statements.

(Refer Slide Time: 35:55)

$$P_f = P(U_{i \in I} E_i)$$

$$= P(E_1 \cup E_2 \cup \dots \cup E_n)$$

$$= \sum_{i=1}^n P(E_i) - \sum_{j=1}^{n-1} \sum_{i=1}^{j-1} P(E_i \cap E_j)$$

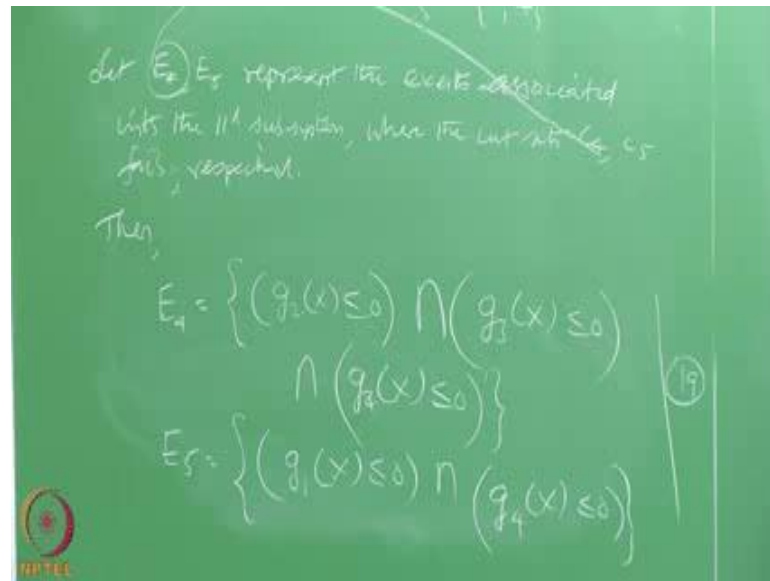

*(I) stands for the minimum cut sets identified from the general system.*  
*along with the probabilities of failure of*  

$$\sum_{i=1}^n P(E_i)$$
  
*Every possible intersection of the cut sets (with appropriate sign)*

Further probability of failure can be then written as probability of union of events. One which can be further read as probability of event 1 union, event 2 union keep on going as event n which then can be written as the sum of probabilities of event i minus the summation of probabilities of event i and event j.

In this argument n c stands for the minimum cut sets identified from the general system. Now the above equation can be solved with summing the probability of failure of each cut set. Let say summation of probabilities of event i along with the probability of failure of every possible intersection of cut sets. So, the above equation is now solved by summing the probability of failure of each subset each. Sorry each cut set given by this expression along with the probabilities of failure of every possible along with the probability of failure of every possible intersection of the cut sets identified of course, using appropriate sign that is very important it is an algebraic summation.

(Refer Slide Time: 38:50)

For the example we are discussing we are discussing 2 cut sets where identified. What are they? They are  $c_4$  which is 2, 3 and 4 and  $c_5$ ; which is 1 and 4, therefore let  $e_4$  and  $e_5$  represent the events associated with the parallel sub system where the cut sets  $c_4, c_5$  fail, now I should say representatively because  $e_4$  is also with  $c_4$  and  $e_5$  with  $c_5$  respectively.

Then one can say  $e_4$  is nothing, but there is nothing, but related to  $c_4$  therefore, 2, 3, 4 are there. Therefore, i can say  $g_2$  of  $x$  less than equal to 0 intersection  $g_3$  of  $x$  less than equal to 0 intersecting  $g_4$  of  $x$  less than equal to 0 that is going to be  $e_4$  and  $e_5$ ; obviously, in the similar pattern is  $e_5$  compress of  $c_5$  is a 1 and 4. So, 1 can say  $g_1$  less than 0 intersecting  $g_4$  less than 0 calls as equation number 19.

(Refer Slide Time: 41:09)

$$P(F) = P(E_4) + P(E_5) - P(E_4 E_5) \quad (20)$$

$$P(E_4) = \Phi_3(-\beta_4/R_4)$$

$$P(E_5) = \Phi_2(-\beta_5/R_5) \quad (21)$$

$$P(E_4 E_5) = \Phi_4(-\beta_4/R_4, -\beta_5/R_5)$$

$$\beta_4 = \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix}$$

$$R_4 = \begin{bmatrix} 1 & \alpha_{12} & \alpha_{13} \\ \alpha_{21} & 1 & \alpha_{23} \\ \alpha_{31} & \alpha_{32} & 1 \end{bmatrix}$$

Therefore, probability of failure is given by probability of failure is p of e 4 plus p of e 5 because, these are the 2 events from the cut sets minus p of e 4, e 5 which is essentially derive based on the rules of probability, what we studied in the first model call equation number 20. So, for explanation p e 4 is nothing, but phi of 3 which has arguments of reliability index b 4 and r 4 p of e 5 is approximately phi of 2 of minus beta 5, r 5 and e 4 e 5 is probability of phi 4 minus beta 4, 5 beta 4, 5 equation number 21.

Where beta 4 is; beta 2, beta 3, beta 4; r 4 is the correlation matrix which is going to be 1, alpha 3, alpha 2, alpha 4, alpha 1, alpha 2, alpha 3, 1; alpha 4, alpha 3, alpha 2, alpha 4, alpha 3, alpha 4, and 1.

(Refer Slide Time: 43:33)

And in this case alpha 2, 3 and alpha 2, 4 again 1 alpha 4, 3 and 1 alpha 3, 4 that is going to make r 4, 5.

Friends, in this lecture we are able to estimate the probability of failure for example, of a minimum cut system taken from the general system, applied the mathematical simplification of converting the non normal variables. So, a normal variate space and variable to estimate the probability of failure using the rules of probability theory what we studied in the first module.

We will extend this discussion further and try to understand how this can be further in detail being done, and then we will take up this application later with a numerical example.

Thank you very much.
