Advanced Structural Analyses
Lecture – 27
Shear Centre II

Friends, we will continue with the discussion on shear centre, this is lecture 27 on module 2 where we are discussing Advanced Structural Analyses, Shear Centre II.

(Refer Slide Time: 00:30)

Example 2

To find V_1

$$V_1 = \int \tau da = \int \frac{VA\bar{y}}{It} da$$

area = $t \cdot x$
 $da = dx \cdot t$
 $\bar{y} = \frac{d}{2}$

$$V_1 = \frac{V}{It} \int_0^b (t \cdot x) \left(\frac{d}{2}\right) dx$$

$$= \frac{V}{It} \int_0^b t \frac{d}{2} x dx$$

$$V_1 = \frac{V}{It} \frac{t \cdot d}{2} \left[\frac{x^2}{2} \right]_0^b$$

$$V_1 = \frac{V t b^2 d}{4I} = V_2 \quad (\text{By symmetry})$$

Neglect shear taken by web.

$C = \frac{t b^2 d}{2I}$

Take moments about C

$$V e = V_1 \frac{d}{2} + V_2 \frac{d}{2}$$

$$V e = \frac{V t b^2 d \times 2}{4I}$$

Diagram: A channel section with top flange width b , thickness t , and depth d . The web thickness is t . The shear center C is located at a distance e from the vertical axis of symmetry. Shear force V is applied downwards at the center. Resultant shear forces V_1 and V_2 are shown acting on the top and bottom flanges respectively. The vertical axis of symmetry is indicated.

Now, we will take out the second example problem, where the section now is a channel which has 1 axis symmetry as marked now; one can say this is axis of symmetry, let us see the dimensions of this is b , thickness t and depth of the section d . Let us say this is my resultant shear force V_1 , this is resultant shear force V_2 , for the applied load V at the shear centre C which is distance e on this axis.

Now to find V_1 ; V_1 is $\tau d a$, which is $\frac{VA \bar{y}}{I t}$ by $d a$, let us consider a strip which is x from here and whose thickness is $d x$. So, area under consideration is going to be t into x and $d a$ is going to be $d x$ into t and \bar{y} the strip distance is going to be $\frac{d}{2}$ that is this distance. So, therefore, now V_1 is v by $I t$, integral $t x d x$ into $\frac{d}{2}$ by $2 a y$ bar so which is then, integrating this from the limits 0 to b . So, v by $I t$ integrating 0 to b ,

t square d by $2 \times d \times x$. V_1 now can be computed as V by $I t$, t square d by $2 \times$ square by 2 0 to b which is $V t$ by $4 I$, b square d that is V_1 .

We also know by symmetry is also equal to V_2 , let us neglect shear taken by the web. So, let us take moments about C . So, V into e which is anti clockwise will be now equal to V_1 into d by 2 , plus V_2 into d by 2 . So, V into e is $V t b$ square d by $4 I$ into 2 , which gives me e as $t b$ square d by $2 I$.

(Refer Slide Time: 06:43)

Example 3
 By symmetry $V_1 = V_5$
 $V_2 = V_4$
 To find V_1 , $V_1 = \int \tau da = \int_0^{b_1} \frac{VQ}{It} da$
 $a = tz$
 $da = t dz$
 $\bar{y} = \left(\frac{h}{2} - b_1 + \frac{z}{2}\right)$
 $V_1 = \int_0^{b_1} \frac{V}{It} (tz) \left(\frac{h}{2} - b_1 + \frac{z}{2}\right) t dz$
 $= \frac{Vt}{I} \int_0^{b_1} \left(\frac{h}{2} - b_1 + \frac{z}{2}\right) z dz$
 $V_1 = \frac{Vt}{I} \left[\frac{h}{2} \left(\frac{z^2}{2}\right) - b_1 \frac{z^2}{2} + \frac{z^3}{6} \right]_0^{b_1}$
 $= \frac{Vt}{I} \left[\frac{h}{2} \left(\frac{b_1^2}{2}\right) - \frac{b_1^3}{2} + \frac{b_1^3}{6} \right]$
 $V_1 = \frac{Vt}{I} \left[\frac{hb^2}{2} - \frac{b^3}{3} \right] = \frac{Vtb^2}{I} \left(\frac{h}{2} - \frac{b}{3} \right)$

Let us take up another example, let us say this is the central line dimensions, this dimension is b , let us say this is b_1 and this is pitch section as uniform thickness t , we agree that this section has 1 axis of symmetry and the shear centre need to lie on this axis, this is the plane of application of V and this becomes by shear centre C , let us say that this is placed at a distance e from here and the shear flow will be like this way. So, let us call this as V_5 let us call this as V_1, V_2, V_3, V_4 and. So, by symmetry we know that V_1 is V_5 and V_2 is V_4 .

Now, I want to find V_1 . So, let us take a strip which is at a distance z , thickness d , we know V_1 is integral $\tau d a$, which is integral $V Q I t da$ for the distance 0 to b_1 because that is the strip value 0 to b_1 . Area is actually t into z and $d a$ is actually t into $d z$, y bar that is the distance of this from here that is y bar, let us say y bar is h by 2 minus b_1 , plus z by 2 because we know this distance is h by 2 , if you say minus b_1 you are here plus z by 2 will give you the distance of this point from here.

So, now let us substitute b_1 integral 0 to b_1 , v by $I t$, $t z$, $t d z$, h by 2 minus b_1 plus z by 2 ; this says $V t$ by I because there are 2 t 's here in the numerator, integral b_1 , h by 2 minus b_1 plus z by 2 into $z d z$. So, V_1 will be $V t$ by I , h by 2 , z square by 2 , minus b_1 z square by 2 , plus z cube 6 limits 0 to b_1 , which is $V t$ by I , h by 2 , b_1 square by 2 , minus b_1 cube by 2 , plus b_1 cube by 6 , which will be $V t$ by I , h b_1 square by 4 , minus b_1 cube by which can be then simplified as $V t b_1$ square by I , h by 4 , minus b_1 by 3 that is b_1 let us say equation 1.

Now, let us compute V_2 for this flange.

(Refer Slide Time: 14:06)

To find V_2

$$A \bar{y} = \left[(b_1 t) \left(\frac{h}{2} - b_1 + \frac{b_1}{2} \right) + (x t) \left(\frac{h}{2} \right) \right]$$

$$= \left(\frac{b_1 t h}{2} - b_1^2 t + \frac{b_1^2 t}{2} \right) + \int x t \frac{h}{2}$$

$Q = x t$
 $da = -dx t$
 $\bar{y} = \frac{h}{2}$

$$V_{y_2} = \frac{V t h}{2 I} \int_0^b x dx = \frac{V t h}{2 I} \frac{b^2}{2} = \frac{V t h b^2}{4 I}$$

$$V_2 = \frac{V t}{I} \left[b_1 \left(\frac{b h}{2} \right) - \frac{b_1^2 b}{2} + \frac{b_1^2 h}{4} \right] \quad \text{--- (1)}$$

Take moment about A: $V_1 e = (V_1 + V_2) b + (V_2 + V_3) \frac{h}{2}$

$$V_2 = 2 V_1 b + 2 V_2 \frac{h}{2}$$

Let us draw this case separately; this is axis of symmetry which is at resistance h by 2 from here, let us consider a strip which is at a distance x from here and thickness $d x$ and we know that this thickness is t and we also know that this dimension is b_1 . So, now, there are 2 areas here let us do for both to find V_2 .

Let us say first let us compute $a y$ bar. So, b_1 into t , into h by 2 , minus b_1 , plus b_1 by 2 that will be the distance of this centre from here, because h by 2 minus b_1 will be here, plus b_1 by 2 will give you this, plus that is for the hatched portion here and for this remaining portion it should be x into t into h by 2 . So, which can be expanded as $b_1 t h$ by 2 , minus b_1 square t , plus b_1 square t by 2 , plus integral of this $x t h$ by 2 for the length 0 to b , let us compute the area is $x t$, da is $d x t$ and y bar for this piece is $s h$ by 2 therefore, V_2 is going to be V_2 let us say star, that is this part horizontal flange this part

is star going to be integral V by $I t$, x t t d x , h by 2 , 0 to b because that is dimension of this 0 to b .

So, which will be $V t h$ by $2 I$, x d x 0 to b , which will give me $V t h$ by $2 I$, b square by 2 this says $V t h b$ square by $4 I$ that is b^2 star, that is this part. So, let us find the total V^2 which will be $V t$ by I , b^2 plus $b h$ by 2 , minus b^2 square by 2 , plus b square h by 4 . So, now, equation numbers 2 . So, taking moments about C not doing more over C , taking movement about A ; where A is this point, we can write V into e which is anticlockwise which will be equal to V_1 plus V_5 into b , plus V_2 plus V_4 into h by 2 , which simply says that it is $2 V_1 b$ plus $2 V_2 h$ by 2 . So, substituting for V_1 and V_2 in terms of V , we can straight away say e will be given by $t b^2$, h square by $2 I$, b^2 plus b by $2 b^2$ minus 4 by 3 , b^2 square by h .

(Refer Slide Time: 20:39)

Example 4

To find V_1 $\int \frac{VQ}{It} dx$ area = tz
 $da = t dz$
 $\bar{y} = \frac{h}{2} + b - z$

$$V_1 = \int_0^b \frac{V}{It} (tz) \left(\frac{h}{2} + b - z\right) t dz$$

$$= \frac{Vt}{I} \left\{ \frac{h}{2} \left(\frac{b^2}{2}\right) + \frac{b^3}{2} - \frac{b^3}{3} \right\}$$

$$= \frac{Vt}{I} \left(\frac{b^2 h}{4} + \frac{b^3}{3} \right)$$

$$V_1 = \frac{Vtb^2}{I} \left(\frac{h}{4} + \frac{b}{3} \right) \quad \text{--- (1)}$$

$$I = \frac{th^3}{12} + \left[\frac{tb^3}{12} + tb \left(\frac{h+b}{2} \right)^2 \right] + \left(\frac{bt^3}{12} + \frac{bt^2 h^2}{4} \right)$$

Let us do one more example, the section is again a special section used for housing electrical cables or cable tree, which is called as a channel bracket section. Let us say the dimensions are marked as b_1 , this is b which is as same as centre to centre, the section has uniform thickness t throughout and (Refer Time: 21:41) dimension is h , as we now agree section as 1 axis of symmetry therefore, the shear centre will lie at this point, let us subject the vertical load here, the shear flow will be this way to oppose the shear, let us call this net resultant as V_1 , this net resultant as V_2 , V_3 , V_4 and V_5 .

Now, to find V_1 we will cut a strip at a distance z from here, let this be $d z$ and for finding V_2 let us cut a strip at a distance x from here let the strip be $d x$. Now to find V_1 , which is integral for the entire area $V Q d a$ by $I t$; now area is $t z$, d area is $t d z$ and y bar is h by 2 , plus b by 1 , minus z by 2 . So, therefore, V_1 will be integral 0 to b by 1 , V by $I t$, z , h by 2 , plus b by 1 minus z by 2 of $t d z$, which is $V t$ by I , h by 2 b by 1 square by 2 , plus b by 1 cube by 2 , minus b by 1 cube by 3 , which can be said as $V t$ by I , b by 1 square h by 4 , plus b by 1 cube by 3 , which is $V t$ by I , h by 4 , plus b by 1 by 3 , that is V_1 .

Now, to compute V_2 take this strip into consideration.

(Refer Slide Time: 25:40)

To find V_2

$$Q = A \bar{y}$$

$$= (b \cdot t) \left(\frac{h}{2} + \frac{b}{2} \right) + t x \left(\frac{h}{2} \right)$$

$$d a = t dx$$

$$V_2 = \frac{V}{I} \int_0^b t \left(\frac{b h}{2} + \frac{b^2}{2} + \frac{x h}{2} \right) t dx$$

$$= \frac{V t}{I} \left(\frac{b h b}{2} + \frac{b^2 b}{2} + \frac{h b^2}{4} \right)$$

Taking moments about A ,

$$(V_2 + V_2) \frac{h}{2} \rightarrow (V_1 + V_2) b = V C$$

$$\checkmark V_2 + 2 \sqrt{V_2} b = 2 \sqrt{V_2} \frac{h}{2} \rightarrow \text{find } C \checkmark$$

So, to find V_2 , now looking for this is an axis of symmetry, I am cutting a strip here, after distance x from here of $d x$. So, we have to look at this area and $A Y$ bar of this separately. So, there are 2 pieces here one is horizontal, one is vertical, let us work out separately. So, Q is actually $A Y$ bar, let us say b by 1 into t is the vertical strip, this distance we know is h by 2 and this of course, we know it is b by 1 therefore, the distance will be h by 2 , plus b by 1 by 2 . Now for the horizontal strip it is simply $t x$ and the distance of this is h by 2 , t being very small we can straight away say that this distance is as same as this distance. So, $d a$ is $t d x$ therefore, V_2 ; V by $I t$ integral 0 to b , t , b by 1 h by 2 , plus b by 1 square by 2 , plus x h by 2 of $t d x$, which can now say it is $V t$ by I , b by 1 h by 2 , plus b by 1 square b by 2 , plus h b square by 4 at substituting the limits.

One can also calculate I for the entire section, we will do it here. So, the moment of inertia for the entire section can be calculated as $t h^3$ by 12, that is for the web $t b^3$ by 12 that is for this portion as well as the above one, then parallel axis theorem $t b^3$ by 12 plus b^3 by 12 the whole square; there are 2 elements of this, plus $b t^3$ by 12, plus $b t h^2$ square by 4 again 2 elements of this. Once I know I now taking moments about point A, we can say $V/2$ plus $V/4$ into $h/2$, because they will cause a clockwise movement about this point $V/2$ will cause a clockwise moment, minus now this going to cause a anticlockwise moment $V/1$ plus $V/5$ of b will be actually equal to this will cause again a clockwise moment, which will be equal to this moment which is V into e . So, one say V into e , plus $2 V/1 b$ because $V/1 V/5$ are identical, it is actually equal to $2 V/2 h$ by 2. So, we have equations for $V/2$ we have $V/1$ and V is a known value, by solving I can find the shear centre distance e which is marked from this point which is calculated. So, e can be updated.

(Refer Slide Time: 31:13)

Example 5
 To find e

$$\tau = \frac{V}{I} \int y da$$

$$= \frac{V}{I} \int_{\beta}^{\theta} (R \cos \theta) R (da)$$

$$\tau = \frac{VR^2}{I} (\sin \theta - \sin \beta)$$

Elemental shear force, $dV = \tau da$
 $dV = \frac{VR^2}{I} (\sin \theta - \sin \beta) d\theta$ $\therefore da = R d\theta$

Let us take one more example which we will take a curved section, let us say this section has an angle which is extended to be 2α and let the radius be R , let from the vertical the strip be β and let us now cut a strip at an angle θ and let this angle be $d\theta$. So, this becomes my axis of symmetry, let us say my load is applied here and let this be the distance e the distance of shear centre.

So, now the objective is to find e ; locate the shear centre for the section, we know Q is a y bar, which is actually prior to that τ is V by $I t$ varying from β to θ $y d$ a because that is my area under consideration, which will be V by $I t$ β to θ , $R \cos \theta$, into R into $t d \theta$, therefore τ is $V R^2$ by I , $\sin \theta$ minus $\sin \beta$ after applying the limits.

Now, the elemental shear force, dV will be $\tau d a$. So, dV will be $V R^2 t$ by $I \sin \theta$, minus $\sin \beta$ $d \theta$ because that is my $d a$ or $d \theta$ because $d a$ is $R d \theta$.

(Refer Slide Time: 34:33)

Moment of this force about the centre

$$dM = \frac{V R^2 t}{I} (\sin \theta - \sin \beta) d\theta$$

Total moment, $M = 2 \int_{\beta}^{\pi/2} \frac{V R^2 t}{I} (\sin \theta - \sin \beta) d\theta$

$$= \frac{2 V R^2 t}{I} \left[-\cos \theta - \sin \theta / 2 \right]_{\beta}^{\pi/2}$$

$\therefore \left(\frac{\pi}{2} - \beta \right) = \alpha$

$$M = \frac{2 V R^2 t}{I} \left[-\cos \pi/2 + \cos \beta - \frac{\pi}{2} \sin \pi/2 + \beta \sin \beta \right]$$

Now, I take moment of this force about the shear centre, let us say dm it is an elementary strip $V R^2 t$ by $I \sin \theta$, minus $\sin \beta$ $d \theta$. So, now, the total moment M will be integral β to π by 2 , please see the limits here its varying from β to π by 2 , but twice $V R^2 t$ by $I \sin \theta$, minus $\sin \beta$ $d \theta$ which gives me $2 V R^2 t$ by I , minus $\cos \theta$ minus $\sin \beta$ θ applying limits β to π by 2 , we also know from the figure that π by 2 minus β is α that is this angle, this angle will be actually α because the total angle is appended is 2α .

So, using this relationship, since π by 2 minus β is α , let us rewrite M as $2 V R^2 t$ by I , minus $\cos \pi$ by 2 , plus $\cos \beta$, minus π by 2 $\sin \beta$, plus $\beta \sin \beta$.

(Refer Slide Time: 36:58)

Handwritten derivation for the moment of inertia M of a circular segment:

$$M = \frac{2VR^4t}{I} \left[\cos\left(\frac{\pi}{2}-\alpha\right) - \frac{\pi}{2} \sin\left(\frac{\pi}{2}-\alpha\right) + \left(\frac{\pi}{2}-\alpha\right) \sin\left(\frac{\pi}{2}-\alpha\right) \right]$$

$$= \frac{2VR^4t}{I} \left[\sin\alpha - \frac{\pi}{2} \cos\alpha + \left(\frac{\pi}{2}-\alpha\right) \cos\alpha \right]$$

$$M = \frac{2VR^4t}{I} \left[\sin\alpha - \alpha \cos\alpha \right]$$

This moment should be equated to Ve

$$Ve = \frac{2VR^4t}{I} (\sin\alpha - \alpha \cos\alpha)$$

$$e = \frac{2R^4t}{I} (\sin\alpha - \alpha \cos\alpha)$$

This says M is $2VR^4t$ by I , $\cos \pi$ by 2 is 0 therefore, $\cos \beta$ can be said as π by 2 minus α , $\sin \beta$ is again $\sin \pi$ by 2 minus α , plus β $\sin \beta$ that is π by 2 minus α multiplied by $\sin \pi$ by 2 minus α , applying trigonometric rules we can say by I this becomes $\sin \alpha$, the second term becomes minus π by 2 $\cos \alpha$, plus π by 2 minus α $\cos \alpha$, which can be $2VR^4t$ by I $\sin \alpha$, minus π by 2 $\cos \alpha$ plus π by 2 α goes away, minus $\alpha \cos \alpha$ that is my M . So, now, this M should be equated to V into e because we are talking about at the centre we have taken moment about this point. So, V into e should be equated. So V into e is $2VR^4t$ by I $\sin \alpha$ minus $\alpha \cos \alpha$.

So, I can now find e as $2R^4t$ by I , $\sin \alpha$ minus $\alpha \cos \alpha$, provided we know how to compute moment of inertia for this segmental piece will be able to compute the shear center distance from the centre of curvature as shown below.

(Refer Slide Time: 39:41)

Example 6 :
 Assuming linear variation of shear in the flanges.

$$\tau_{max1} = \frac{V}{2I_z} (29 \times 2) \left(60 - \frac{29}{2}\right)$$

$$= \frac{2639 V}{2I_z}$$

$$\tau_{av1} = \frac{2639 V}{4I_z}, \quad V_1 = \frac{2639}{4I_z} (29 \times 2) = 38265.5 \frac{V}{I_z}$$

$$\tau_{max2} = \frac{V}{2I_z} (40 \times 2) 60 = \frac{2400 V}{I_z}$$

$$\tau_{av2} = \frac{1200 V}{I_z}, \quad V_2 = \frac{1200 V}{I_z} (40 \times 2) = 96 \times 10^3 \frac{V}{I_z}$$

Take moments about A ; $(V_1 \times 2) 40 + (V_2 \times 2) 60 = V e$

The diagram shows a channel section with a web of thickness 2 and height 120. The flanges have a width of 40 and a thickness of 2. The centroid is at a distance of 60 from the outer edge of the flanges. A shear force V is applied at the top center. The shear center is at a distance e from the web centerline. The shear flow is assumed to vary linearly in the flanges.

Let us take one more example and see how quickly we can compute the shear centre. Let us do by some other quick technique to find down the shear centre, take a same example of a channel, but we do this problem slightly in a different manner.

Let us say this dimension is 30, this dimension is 40 and this dimension is 120 and the thickness is 2, we know that it has 2 axis if marked like this out of which one is axis of symmetry. So, shear centre need to lie on this let us say this is my plane web the resultant forced need to be applied. So, I take this distance as e. So, the shear flow says that is V 1, this is V 2 and this also V 1 and this is also V 2 by symmetry we already know this assuming linear variation of the shear in the webs.

So, assuming linear variation of shear in the flanges tau max 1 is actually let us say the force V is applied; V by I z thickness is let us say 2 as V I t. So, 29 into 2 is the area of this t is no this one, the distance could be minus 29 by 2 which gives me 2639 V by 2 I z therefore, tau average will be half of this 2639V by 4 I z because we have assumed a linear variation, similarly tau max 2 that is for this piece will be V by 2 I z, the piece area is 40 into 2 and the distance of cg is 60, which gives me 2400V by I z. So, tau average 2 will be 1200 V by I z. Now I can easily find V 1 is 2339 by 4 I z into this area 29 into 2 which is nothing, but 38265.5 V by I z and V 2 is 1200 V by I z into the area this is V 40 into 2 which gives me 96, 10 power 3 V by I z. So, now, I have V 1 and V 2.

Let us take moments about A; we know it is going to be V_1 into 2 into 40 because V_1 and V_5 are same, plus clockwise, so plus V_2 into 2 into 60, that should be equal to V into e .

(Refer Slide Time: 44:38)

The image shows a digital notepad with the following handwritten work:

$$\Rightarrow 38265.5 \frac{V}{I_z} + 96 \times 10^3 \frac{V}{I_z} = V e$$

$$\Rightarrow 3061240 + 11.52 \times 10^6 = e I_z$$

$$I_z = \left\{ \frac{2 \times 29^3}{12} + 29 \times 2 \left(60 - \frac{29}{2} \right)^2 \right\} \times 2$$

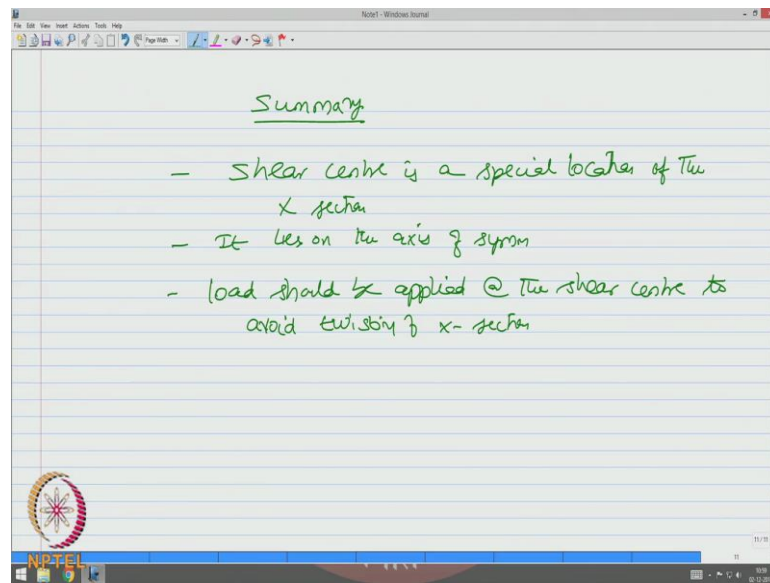

$$+ \left\{ \frac{40 \times 2^3}{12} + 40 \times 2 \times 60 \right\} \times 2$$

$$+ \frac{2 \times 120^3}{12} = 11.12 \times 10^5 \text{ mm}^4$$

Substituting the above eqn, $e = 13.1 \text{ mm}$

Let us substitute back $38265.5 V$ by I_z into 80, plus $96 \times 10^3 V$ by I_z into 120 V into e , V goes away therefore, 3061240 , plus 11.52×10^6 will be $e I_z$. So, now, let us see how to compute I_z quickly from this figure, I_z will be 2 into 29 cube by 12 , plus parallel axis theorem 60 minus 29 by 2 the whole square 2 such pieces, plus $V d q$ by 12 that is 40×2 cube by 12 , plus a k square, 40 into 2 into 60 square again 2 such pieces, plus of course, whether $b d$ cube by 12 , which I get I_z as $11.12 \times 10^5 \text{ mm}^4$ substituting in the above equation e is 13.1 mm .

(Refer Slide Time: 46:33)

So, friends let us look at the summary, shear centre is a special location of the cross section. It lies on the axis of symmetry preferably load should be applied at the shear centre to avoid twisting of the cross section. We have seen examples to estimate shear centre for sections which has 1 axis of symmetry because shear centre will lie on that axis. We will also take up examples to estimate or locate the shear centre where there are no axes of symmetry how they can be obtained in the next lecture.

Thank you.
