for a steady state response,
dynamic magnification factor, $D = \frac{1}{\sqrt{(1-\beta^2)^2 + 4\zeta^2\beta^2}}$

where $\beta =$ ratio of forcing freq to natural freq
 $\zeta =$ damping ratio

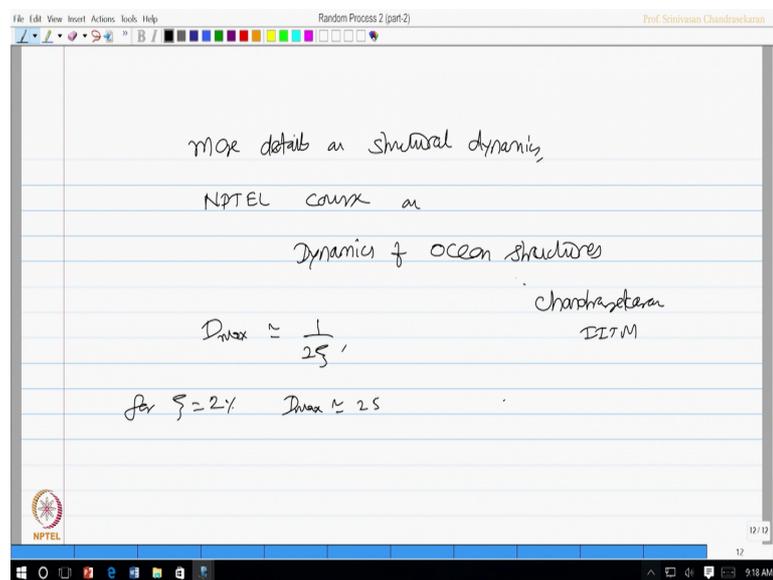

For a weakly damped system, it can be shown that
 $D_{max} \approx \frac{1}{2\zeta}$

The screenshot also shows a Windows taskbar at the bottom with the time 9:17 AM and a Windows logo on the left. The whiteboard interface includes a toolbar with various drawing tools and a menu bar at the top with 'File Edit View Insert Actions Tools Help'.

For a steady state response, we know the dynamic magnification factor which we called as D is given by this expression $\frac{1}{\sqrt{1 - \beta^2 + 2\zeta\beta}}$ where β is the ratio of forcing frequency to the natural frequency of the system and ζ is the damping ratio. So, standard expression in structural dynamics.

So, let us say for a weakly dampened systems, it can be easily shown that the maximum value of the dynamic amplification factor will be bounded by $\frac{1}{2\zeta}$ for the benefit of the listeners if you really wanted to look at more details on structural dynamics.

(Refer Slide Time: 01:49)

I shall refer you to an NPTEL course on dynamics of ocean structures through IITM Madras portal; please look at this course in detail, if you really wanted to know more about the derivations what we did in the last slide.

Having understood that we know that the maximum amplification factor will be governed by one way to ζ so, for ζ about 2 percent which is a very common case D_{max} is approximately about 25; what does it mean?

(Refer Slide Time: 02:52)

This implies that
even small oscillation forces may lead to
large responses, because it is amplified ✓

It is better to introduce a complex valued function

$$H(\omega) = |H(\omega)| e^{-i\phi} \quad (1)$$

Hence $u(t) = |H(\omega)| P_0 \cos(\omega t - \phi)$ (2)

where $u(t)$ steady state response.
 $H(\omega)$ - amplitude amplification
 ϕ - phase shift

This means that even small oscillation forces may lead to large responses because it is amplified. So, even for small oscillation forces, it may lead to larger responses because there is an amplification happening in such situation it is always better to introduce a complex function or a complex valued function which can account for the phase lag. So, that function typically looks like $H(\omega)$ is mod value of $H(\omega)$ $e^{-i\phi}$, I call this equation as 11.

Hence the response function what you are interested in will be given by the transfer function multiplied by $P_0 \cos(\omega t - \phi)$ where $u(t)$ is the steady state response and $H(\omega)$ gives the amplitude amplification where as ϕ gives you the phase shift having said this.

(Refer Slide Time: 04:54)

Example, If $H(\omega) = 0.001$, @ any specific frequency ω
this is true then
force amplitude of 100N will give rise to
displacement of $(100 \times 0.001) = 0.1\text{m}$ @ this specific
frequency
Hence for $U_p(t) = P \cos(\omega t - \phi)$, be a
generalized expression of steady state response

Let us quickly see for example, if $H(\omega)$ for a given linear system is 0.001 at any specific frequency ω , this is true because you know $H(\omega)$ is a function of ω . So, for any specific frequency, let us say 2ω 0.001, then your force amplitude of let us say 100 Newton will give rise to displacement of hundred into 0.001 which will be point one meters at this specific frequency.

So, the transfer function is very useful to connect the response and the load given to an system at a specific frequency hence for the particular integral $u_p(t)$ which is $\rho \cos(\omega t - \phi)$ be a generalized expression of steady state response.

(Refer Slide Time: 06:50)

$$\frac{F}{x} = \frac{F}{(P_0/k)} \equiv D$$

$$\therefore F = D \cdot \left(\frac{P_0}{k}\right)$$

$$U(t) = \frac{P_0}{k} \frac{1}{\sqrt{(1-\beta)^2 + (2\zeta\beta)^2}} \cos(\omega t - \phi) \quad (13)$$

$$U(t) = |H(\omega)| P_0 \cos(\omega t - \phi) \quad (12)$$

The rho by x static can be simply said as rho by P 0 by k which is the D value therefore, rho can be simply said as D of P 0 by k. So, now, u P of t is actually P 0 by k 1 by root of one minus beta square square plus 2 zeta beta square of cos omega t minus phi, I call this equation number 13. Let us rewrite equation number 12 which we already had here equation number 12 which we already had here let us compare equation 12 is ut is H omega P 0 cos omega t minus phi.

(Refer Slide Time: 08:10)

By comparing G(13) & G(12), we can draw:

$$H(\omega) = \frac{1}{k \sqrt{(1-\beta)^2 + (2\zeta\beta)^2}}$$

$H(\omega)$ - Transfer function or
 frequency response function connects \vec{r}
 load (forcing function) to the response

By comparing these 2 equations, we can observe that $H(\omega)$ can be simply $1/k$ of root of $1 - \beta^2 + 2\zeta\beta$. $H(\omega)$ is called the transfer function or also called as frequency response function which connects load or the forcing function and the response. So, that is a very interesting equation which we derived.

Let us further pay attention more to explaining this equation.

(Refer Slide Time: 09:28)

The image shows a digital whiteboard with handwritten text and a mathematical equation. The text reads: "It is seen that $H(\omega)$ is proportional to DAF (D)", "(a) $H(\omega)$ contains all relevant information about Dynamic amplification and phase shift; (b)", and "Hence". Below this, the equation is written as $H(\omega) = \frac{1}{k} \frac{1}{\sqrt{(1-\beta^2)^2 + (2\zeta\beta)^2}} e^{-i\phi}$. The whiteboard interface includes a menu bar at the top with options like File, Edit, View, Insert, Actions, Tools, Help, and a toolbar with various drawing tools. The bottom of the whiteboard shows a Windows taskbar with the time 9:35 AM.

It is seen that $H(\omega)$ is proportional to the dynamic amplification factor t that is $H(\omega)$ contains all relevant information about the dynamic amplification and phase shift. Phase shift is of course, given by ϕ . Hence $H(\omega)$ as we said is $1/k$ of root of $1 - \beta^2 + 2\zeta\beta$ e to the power of minus $i\phi$.

There is a specific reason why we use e power minus $i\phi$ in this equation.

(Refer Slide Time: 10:59)

$$i) \frac{d}{dt} (e^{i\phi}) = i \frac{d\phi}{dt} e^{i\phi} \quad \text{as } e^{i\phi} \text{ factor doesn't change}$$

$$ii) e^{i\phi_1} e^{i\phi_2} = e^{i(\phi_1 + \phi_2)} = e^{i\phi_3} \quad \text{product of 2 factors of type } e^{i\phi} \text{ lead to product of same kind}$$

Hence
$$H(\omega) = \frac{1}{k} \frac{1}{\sqrt{(1-\beta^2)^2 + 2\zeta\beta^2}} e^{-i\phi}$$

So, d by dt of e power i phi is i d by dt of again e phi that is e power i phi factor does not change that is one important point. Secondly, e i phi 1 e i phi 2 can be e i phi 1 plus 2 which is as same as e i phi 3 that is product of 2 factors of type e i phi lead to product of same kind. So, that is the advantage we have when you use e i phi in this equation. Hence H omega is 1 by k root of one minus beta square square plus 2 zeta beta square of e minus i phi represents the complete information about the dynamic amplification and the phase shift which connects the load and the response of a given system having said this.

(Refer Slide Time: 12:57)

$$H_{Fx(\omega)} = \frac{1}{k} \quad \text{and}$$

$$m_x = \frac{m_f}{k}$$

Hence
$$m_x = H_{Fx(\omega)} \cdot m_f$$

mean value of the response is equal to mean value of the load multiplied by the system response to a static load of unit size

$$m_x = H_{Fx(\omega)} \cdot m_f \quad (14)$$

Let us say $H F x 0$ is 1 by k and mean x is m_f by k hence m_x is $F \times 0$ of $m F$ what does it mean is the mean value of the response is equal to mean value of the load multiplied by the system response to a static load of unit size. So, that is a great advantage of interpreting the response and the load function. So, one can now say m_x is $H F x 0$ of $m F$ equation 14.

(Refer Slide Time: 14:23)

Summary

$$m_x = H F x 0 m_f$$

- Explaining Random process, further
- Transfer function, Impulse response function
connects load / response
- applied to an example of multi-degree freedom - dynamic system

$$H(\omega) = \frac{1}{k} \frac{1}{\sqrt{1 - \left(\frac{\omega}{\beta}\right)^2 + \left(\frac{\omega}{\beta}\right)^4}} e^{-i\phi}$$

Let us quickly see what summary we learnt in this lecture. We started with explaining the random process further we explained the transfer function or the impulse response function which connects the load and the response.

We also applied this to an example problem of multi degree freedom system in dynamic systems, then we derive the transfer function as simply the proportion of the dynamic amplification factor and we said that the mean value of the response will be given by a simple relation which is expressed here.

So, friends will continue this lecture to take it more advanced in terms of auto covariance of response processes then from that we will try to derive what we generally use as response spectrum in stochastic analysis.

Thank you very much.
