Lecture - 37
Waveguides

We have been discussing the properties of waveguides. As we have seen that waveguides are essentially conduits through which electromagnetic energy is transmitted from one point to another. So, we had earlier discussed a waveguide which was basically two semi infinite metallic planes. Today, we will be discussing initially the rectangular waveguides which we introduced last time.

(Refer Slide Time: 00:52)

So, it is basically one of the dimensions is of still infinite, but otherwise we have two-dimensions namely it is a rectangular parallelepiped of infinite length, cross section being a by b in the x and y direction, and z direction is the direction in which the wave would propagate.

(Refer Slide Time: 01:17)

ELECTROMAGNETIC THEORY

Rectangular waveguide

$\frac{\partial}{\partial y} H_z + \gamma H_y = i\omega \epsilon E_x$ $-\gamma H_x - \frac{\partial}{\partial x} H_z = i\omega \epsilon E_y$ $\frac{\partial}{\partial x} H_y - \frac{\partial}{\partial y} H_x = i\omega \epsilon E_z$	$\frac{\partial}{\partial y} E_z + \gamma E_y = -i\omega \mu H_x$ $-\gamma E_x - \frac{\partial}{\partial x} E_z = -i\omega \mu H_y$ $\frac{\partial}{\partial x} E_y - \frac{\partial}{\partial y} E_x = -i\omega \mu H_z$
---	---

Prof. D K Ghosh, Department of Physics, IIT Bombay

We had seen that the Maxwell's equations which we had I will just illustrate one of them which was essentially...

(Refer Slide Time: 01:29)

$$\nabla \times E = -\mu \frac{\partial H}{\partial t} = -i\omega \mu \vec{H}$$

$$\nabla \times H = \epsilon \frac{\partial E}{\partial t}$$

$$E \sim e^{i\omega t}$$

$$\frac{\partial}{\partial z} \sim -\gamma e^{-\gamma z}$$

For example Del cross of E equal to minus well d b by d t, but I will write it as minus mu d H by d t. There are no currents or sources. No displacement currents del cross H. Now, as there are no currents so there is no current term here is epsilon d E by d t. And what we are going to do is to take as before the time dependence as E or H they go as e to the power i omega t. As a result this d b by d t that gives you that results in essentially a

multiplication by i times ω . So, as a result you can see the first equation here which is essentially this equation, because this became minus i omega times μ times H .

So, if you take its x components it will become $\nabla \times E$'s x components and $\nabla \times H$'s x component is as you can see here $\frac{\partial}{\partial y} E_z$ minus $\frac{\partial}{\partial z} E_y$, but we have seen that since the propagation direction is z direction. So, $\frac{\partial}{\partial z}$ essentially means multiplication by minus γ , because the propagation goes as $e^{-\gamma z}$ to the power minus γz . And therefore, this equation became $\frac{\partial}{\partial y} E_z$ plus γ times E_y is this. Similarly, this is our Faraday's law where well this is, this was Faraday's law and this is the ampere Maxwell's law.

So, this is $\nabla \times H$ x component which is $\frac{\partial}{\partial y} H_z$ minus $\frac{\partial}{\partial z} H_y$ which is same as plus γ times H_y is $i \omega \epsilon E_x$ and I have written down essentially all the six equations, six components. I have three components of magnetic field and three components of the electric field in this transparency. Now, so what we want to do essentially is to realize that these six equations I can cast them such that every component. So, I have six components. So, I will choose any two components for example, I will choose E_z and H_z and I can manipulate these equations to write them with each component explicitly in terms of the z component of E and H only. So, we had talked about it last time, but let us go through it again.

(Refer Slide Time: 04:27)

The image shows a handwritten derivation on a transparency slide. The equations are as follows:

$$\nabla \times E = -\mu \frac{\partial H}{\partial t} = -i\omega\mu H$$

$$\nabla \times H = \epsilon \frac{\partial E}{\partial t}$$

Assuming a time-harmonic field, $E \sim e^{i\omega t}$, the time derivative becomes $\frac{\partial}{\partial t} \sim -\gamma$, so $\frac{\partial}{\partial z} \sim -\gamma$.

$$i\omega \epsilon E_x = \gamma H_y + \frac{\partial}{\partial y} H_z$$

$$= \frac{\gamma}{i\omega\mu} \left(E_x + \frac{\partial}{\partial z} E_z \right) + \frac{\partial}{\partial y} H_z$$

In the bottom left corner of the slide, there is a logo for NIPTEIL.

So, this equation which we talked about for example the x component of the electric field $i\omega\epsilon E_x$, this is this equation and that is $\nabla \times \mathbf{H}$'s x component and which is, as we have seen x component meanings $\frac{\partial}{\partial y} H_z$ and $\frac{\partial}{\partial z} H_y$ minus $\frac{\partial}{\partial x} H_z$ which is plus γH_y and plus $\frac{\partial}{\partial y} H_z$. So, what I do next in this that this H_y which can from here that is the y component of this, I will write it. So, I already have a γ and you can see that if I take y component of this equation, I will essentially get I divide it by 1 over $i\omega\mu$ and y component means $\frac{\partial}{\partial z} E_x$ minus $\frac{\partial}{\partial x} E_z$ and therefore, this equation becomes γ by $i\omega\mu$ times E_x plus $\frac{\partial}{\partial x} E_z$ plus $\frac{\partial}{\partial y} H_z$.

(Refer Slide Time: 05:58)

The slide displays the following equations:

$$i\omega\epsilon E_x = \gamma H_y + \frac{\partial}{\partial y} H_z$$

$$= \frac{\gamma}{i\omega\mu} \left[E_x + \frac{\partial}{\partial x} E_z \right] + \frac{\partial}{\partial y} H_z$$

$$\left(i\omega\epsilon - \frac{\gamma}{i\omega\mu} \right) E_x = \frac{\gamma}{i\omega\mu} \frac{\partial}{\partial x} E_z + \frac{\partial}{\partial y} H_z$$

$$E_x = -\frac{\gamma}{k^2} \frac{\partial}{\partial x} E_z - \frac{i\omega\mu}{k^2} \frac{\partial}{\partial y} H_z$$

$$k^2 = (\gamma^2 + \omega^2\mu\epsilon)$$

The slide also features the NIPTE logo and the text: Prof. D.K Ghosh, Department of Physics, IIT Bombay.

And now what I do is this that there is E_x there and that I write down again by writing down what is this. So, you write notice that I can write this E_x in terms of for example, I could eliminate E_x from these two equations and write them in terms of the other components. So, if you do all that then it turns out, if you do all that this is a bit of an algebra, but fairly straight forward that you can write E_x in terms of the derivative of E_z and H_z .

So, I have chosen for no particular reason, but because of the fact that the z component z direction is my direction of propagation. I have written E_x in terms of derivative of E_z and derivative of H_z . And if you simplified all these, this is the way the equation works

out where k^2 is $\gamma^2 + \omega^2 \mu \epsilon$. This is and and this you can do for each one of the other components that is H_x and H_y .

(Refer Slide Time: 07:11)

ELECTROMAGNETIC THEORY

Rectangular waveguide

$$E_x = -\frac{\gamma}{k^2} \frac{\partial}{\partial x} E_z - \frac{i\omega\mu}{k^2} \frac{\partial}{\partial y} H_z$$

$$E_y = -\frac{\gamma}{k^2} \frac{\partial}{\partial y} E_z - \frac{i\omega\mu}{k^2} \frac{\partial}{\partial x} H_z$$

$$H_x = \frac{i\omega\epsilon}{k^2} \frac{\partial}{\partial y} E_z - \frac{\gamma}{k^2} \frac{\partial}{\partial x} H_z$$

$$H_y = -\frac{i\omega\epsilon}{k^2} \frac{\partial}{\partial x} E_z - \frac{\gamma}{k^2} \frac{\partial}{\partial y} H_z$$

$$k^2 = (\gamma^2 + \omega^2 \mu \epsilon)$$

NIPTEIL

Prof. D K Ghosh, Department of Physics, IIT Bombay

And this gives you a complete list of the equations where E_x , E_y , H_x and H_y are written in terms of the derivatives of E_z and H_z only. And other than $\omega \epsilon$ and μ which are of course, there we have one quantity there which is k^2 which is appearing as $\gamma^2 + \omega^2 \mu \epsilon$. Now, this is the set of equations.

(Refer Slide Time: 07:42)

ELECTROMAGNETIC THEORY

Rectangular waveguide
TEM mode cannot propagate
TE Mode : Helmholtz equation

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + k^2 \right) H_z(x, y) = 0$$

$$H_z(x, y, z) = H_z(x, y) e^{-\gamma z}$$

Solve by separation of variables.

$$H(x, y) = X(x)Y(y)$$

$$Y \frac{\partial^2 X}{\partial x^2} + X \frac{\partial^2 Y}{\partial y^2} + k^2 XY = 0$$

$$\frac{1}{X} \frac{\partial^2 X}{\partial x^2} + k^2 = -\frac{1}{Y} \frac{\partial^2 Y}{\partial y^2} = k_y^2$$

NIPTEIL

Prof. D K Ghosh, Department of Physics, IIT Bombay

Now, what I will do now is this that now decides the following, that we define what we called modes of propagation. Now, this is done by selecting or rather classifying these solutions in terms of such propagations for which the z component of electric field is equal to 0 that is one group. z component being the direction of propagation if z component of the electric field namely E_z becomes equal to 0, it means that the electric field is transverse. So, this is called transverse electric solution T E. We had seen this earlier also and similarly, another group would be T z T m.

Namely transverse magnetic field for which the H_z is equal to 0 and E_z is not equal to 0, and we had seen earlier that in case of the parallel plate waveguides there are also very special solutions for which both E_z and H_z were equal to 0 and this we called as the transverse electromagnetic or T E M mode. But we will see that was a rather special case in case of parallel plate wave guides, but in this case we do not have such a situation.

(Refer Slide Time: 09:23)

2

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \gamma^2\right) E_z = -\omega^2 \mu \epsilon E_z$$

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + k^2\right) H_z(x, y) = 0$$

$$H_z(x, y) = X(x)Y(y)$$

$$Y \frac{\partial^2 X}{\partial x^2} + X \frac{\partial^2 Y}{\partial y^2} + k^2 XY = 0$$

$$\frac{1}{X} \frac{\partial^2 X}{\partial x^2} + \frac{1}{Y} \frac{\partial^2 Y}{\partial y^2} + k^2 = 0$$

$$\frac{1}{X} \frac{\partial^2 X}{\partial x^2} + k^2 = -\frac{1}{Y} \frac{\partial^2 Y}{\partial y^2} = k_y^2$$

$$k_x^2 = k^2 - k_y^2$$

NPTEL

So, coming back to our equation, the equation that we had for the components of the electric field that is the Helmholtz equation was basically $\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$ which is nothing but γ^2 times your any component of the electric field. Actually it is minus γ^2 , because E to the power. Let us write it as γ^2 because E to the power minus γ^2 we have taken, but if this is propagating actually this will be $i\beta$. Therefore,

it will come to that side and that any component let us say E_x that is equal to $-\omega^2 \mu \epsilon E_x$. This was the equation that we had.

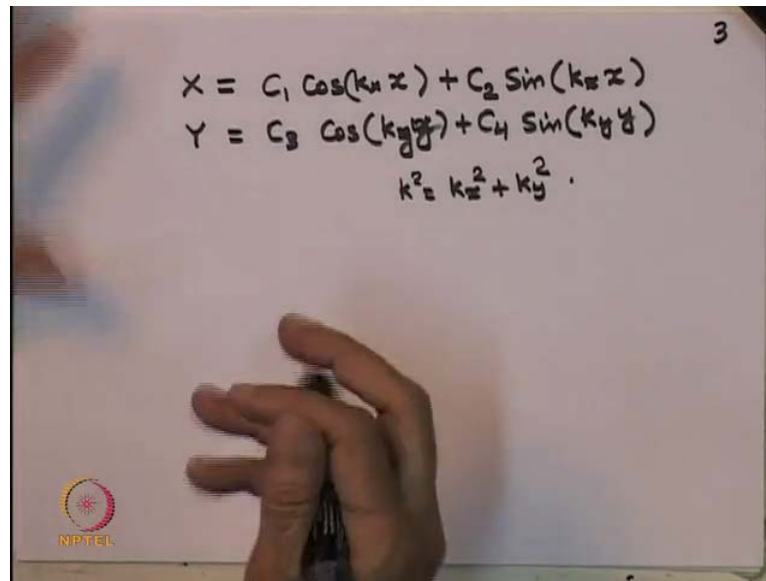

So, as a result what you are getting is this that if you bring this to that side you find that I get $d^2 x/dt^2 + \omega^2 \mu \epsilon x = 0$. If you recall this we had defined as k^2 . Therefore, this is k^2 times any component of electric field, but we are interested in let us say we are talking about TE mode for which E_z is equal to 0.

So, every solution can be written in terms of H_z only. So, this quantity is equal to 0 and H_z because z direction is basically infinite. So, the only dependence it can have is on x and y and that quantity is equal to 0. So, this is the equation for which we need a solution. So, what we said is that you can solve this equation by what is known as separation of variable. So, $H_z(x, y)$ you write it as some quantity X which depends upon x only and some quantity Y which depends upon y only. So, you plug this in because this depends only on x . So, what you find is $Y d^2 X/dx^2 + X d^2 Y/dy^2 + k^2 X Y = 0$.

Now, if you divide this equation by $X Y$ all through you get $1/X d^2 X/dx^2 + 1/Y d^2 Y/dy^2 + k^2 = 0$. Now, we are going to do this technique inferentially is known as separation of variable. So, you notice one thing that I can write this equation as equal to $1/X d^2 X/dx^2 + k^2 = -1/Y d^2 Y/dy^2$. Now, notice one thing this quantity depends upon x only, this quantity depends upon y only and you want for whatever X and Y these two must always be equal.

Now, obviously this is possible if each one of them is a constant and let's call that constant as equal to k_y^2 . So, this plus, this is equal to that is equal to k_y^2 . Now, so as a result you notice that these equations are well known equations to us. For instance this equation is familiar to us in simple harmonic motion because this tells me $d^2 Y/dy^2 + k_y^2 Y = 0$, so as a result my solution for X and Y . Now, and the same thing is true for this quantity also. What you could do is you could define a quantity which is k_x^2 which is such that it is equal to $k^2 - k_y^2$.

(Refer Slide Time: 14:03)

$$X = C_1 \cos(k_x x) + C_2 \sin(k_x x)$$
$$Y = C_3 \cos(k_y y) + C_4 \sin(k_y y)$$
$$k^2 = k_x^2 + k_y^2$$

So, as a result both of them have the same structure and my solution to these equations then become X is some constant C_1 cosine $k_x x$ plus C_2 sin $k_x x$. And likewise capital Y is C_3 cosine $k_y y$ plus C_4 sin $k_y y$. So, my total solution is the product of this with this. In other words this is a product of terms like cosine cosine, cosine sin, sin cosine and sin sin. So, this is this is what I have got. Now, and as we have seen that k^2 is equal to k_x^2 plus k_y^2 . So, once I have got this equation. So, I am writing down solution to my H z, H z because we have taken TE mode so E_z is equal to 0. So, H z is essentially a function of this into this.

Now, let us look at how to determine some of these things. The thing that you have to realize is this that if you take for example, go back to the picture of the rectangular parallelepiped. So, notice this is the z direction is infinite and so here I have got the x y plane for example, x is equal to 0 here. Now, these planes namely x is equal to 0 x is equal to a, y is equal to 0 y is equal to a on these surfaces my tangential component of the electric field must be equal to 0. And notice this that my tangential components will be related to or will be equal to the E_x or E_y , because I have got these surfaces. For example this surface is in the x y plane, and therefore this is at z equal to 0. So, let us look at what does it give me.

(Refer Slide Time: 16:30)

ELECTROMAGNETIC THEORY

**Rectangular waveguide
TE Mode – Boundary Conditions**

$$E_x = -\frac{i\omega\mu}{k^2} \frac{\partial}{\partial y} H_z = 0 \text{ for } y=0, b$$
$$E_y = -\frac{i\omega\mu}{k^2} \frac{\partial}{\partial x} H_z = 0 \text{ for } x=0, a$$
$$H_z(x, y, z) = C \cos\left(\frac{m\pi}{a} x\right) \cos\left(\frac{n\pi}{b} y\right) e^{-\gamma z}$$

 NIPTEIL

Prof. D.K Ghosh, Department of Physics, IIT Bombay

So, take for example, E_x . Now, E_x is the electric field which is essentially the tangential component of the electric field at y is equal to 0 and at y is equal to b . Now, if we looked up the set of equations that we had written down, the E_x for the TE mode namely if E_z is equal to 0 works out to some constant d by dy of H_z . Now, remember this quantity has to be equal to 0 for y is equal to 0 as well as y is equal to b . What it implies is at y equal to 0 and y is equal to b my derivative of H_z with respect to y must be equal to 0. Remember, that my H_z is a function of, consists of four terms cosine $k_x x$ sin cosine $k_y y$ cosine $k_x x$ into sin $k_y y$ etcetera. Now, if you want the derivative of H_z with respect to y to become equal to 0. So, it goes back here.

(Refer Slide Time: 17:45)

ELECTROMAGNETIC THEORY

**Rectangular waveguide
TE Mode : Helmholtz equation**

$$\frac{1}{X} \frac{\partial^2 X}{\partial x^2} + k^2 = -\frac{1}{Y} \frac{\partial^2 Y}{\partial y^2} = k_y^2$$

$$X = C_1 \cos k_x x + C_2 \sin k_x x$$

$$Y = C_3 \cos k_y y + C_4 \sin k_y y$$

$$k_x^2 = k^2 - k_y^2$$

Prof. D.K Ghosh, Department of Physics, IIT Bombay

So, my let me write down what is x into y which is my H z.

(Refer Slide Time: 17:51)

3

$$X = C_1 \cos(k_x x) + C_2 \sin(k_x x)$$

$$Y = C_3 \cos(k_y y) + C_4 \sin(k_y y)$$

$$k^2 = k_x^2 + k_y^2$$

$$H_z = XY = C_3 C_1 \cos k_x x \cdot \cos k_y y$$

$$+ C_1 C_4 \cos k_x x \sin k_y y$$

$$+ C_2 C_3 \sin k_x x \cos k_y y$$

$$+ C_2 C_4 \sin k_x x \sin k_y y$$

This is C 1 cosine k x x into C 3 cosine k y y plus C 1 cosine k x x C 4 sin k y y plus C 2 into C 3 sin k x x cosine k y y plus C 2 into C 4 sin k x x into sin k y y. Now, let us look at what are we trying to say. We are saying that derivative of this derivative of this with respect to y should be 0. Now, if you are differentiating with respect to y this term for instance will give you k y sin k y y. This term will give you k y cos k y y and like this.

Now, you want that for y is equal to 0 this term should give me 0. So, that now this has become sin k y y. So, I do not have a problem with this term becoming equal to 0.

Now, so what am I actually left with? You notice that the the term that I must have, this will tell me that I must have C 3 into C 1 this term must become equal to 0 etcetera. Now, if you do that than ultimately you are left with because these are the four conditions to be satisfied. Ultimately you are left with that I can have H z only given in terms of this type of an equation. That is C times cosine m pi by a times x times cosine n pi by b times y and remember my boundary conditions are that the tangential component of the electric field which comes as derivatives of H z. And the normal component of the magnetic field they will be 0 on the plates.

So, that that tells me that H z is just a product of cosine into cosine. And these facts that the k x and k y becoming equal to m pi by a and n pi by b is because I want these electric fields to vanish at x is equal to a as well as y is equal to b.

(Refer Slide Time: 20:48)

ELECTROMAGNETIC THEORY

**Rectangular waveguide
TE Mode – Boundary Conditions**

$$H_z(x, y, z) = C \cos\left(\frac{m\pi}{a} x\right) \cos\left(\frac{n\pi}{b} y\right) e^{-\gamma z}$$

$$k^2 = \omega^2 \mu \epsilon + \gamma^2 = \left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2$$

NIPTTEL

Prof. D K Ghosh, Department of Physics, IIT Bombay

So, as a result if you now want to write down your full equations H z which is a function of x y z is this solution which we have just now obtained. Times e to the power minus gamma z and k square which we had seen is omega square mu epsilon plus gamma square k square is k x square which is m pi by a whole square and plus k y square which is n pi by b whole square. So, these these are my solutions for H z and E z is equal to 0.

(Refer Slide Time: 21:22)

ELECTROMAGNETIC THEORY

Rectangular waveguide

$$E_x = -\frac{i\omega\mu}{k^2} \frac{\partial}{\partial y} H_z = C \frac{i\omega\mu}{k^2} \frac{n\pi}{b} \cos\left(\frac{m\pi}{a}x\right) \sin\left(\frac{n\pi}{b}y\right) e^{-\gamma z}$$

$$E_y = \frac{i\omega\mu}{k^2} \frac{\partial}{\partial x} H_z = -C \frac{i\omega\mu}{k^2} \frac{m\pi}{a} \sin\left(\frac{m\pi}{a}x\right) \cos\left(\frac{n\pi}{b}y\right) e^{-\gamma z}$$

$$H_x = -\frac{\gamma}{k^2} \frac{\partial}{\partial x} H_z = C \frac{\gamma}{k^2} \frac{m\pi}{a} \sin\left(\frac{m\pi}{a}x\right) \cos\left(\frac{n\pi}{b}y\right) e^{-\gamma z}$$

$$H_y = -\frac{\gamma}{k^2} \frac{\partial}{\partial y} H_z = C \frac{\gamma}{k^2} \frac{n\pi}{b} \cos\left(\frac{m\pi}{a}x\right) \sin\left(\frac{n\pi}{b}y\right) e^{-\gamma z}$$

$$k^2 = (\gamma^2 + \omega^2 \mu \epsilon)$$

Prof. D K Ghosh, Department of Physics, IIT Bombay

So, I will just leave this transparency for some time, this tells you that once you have got H_z of z you can obtain E_x , E_y , H_x and H_y purely in terms of the H_z . So, these are the things which are there.

(Refer Slide Time: 21:47)

ELECTROMAGNETIC THEORY

Rectangular waveguide- TE Modes

$$k^2 = k_x^2 + k_y^2 = \left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2 = \gamma^2 + \omega^2 \mu \epsilon$$

$$\gamma = \sqrt{\left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2 - \omega^2 \mu \epsilon}$$

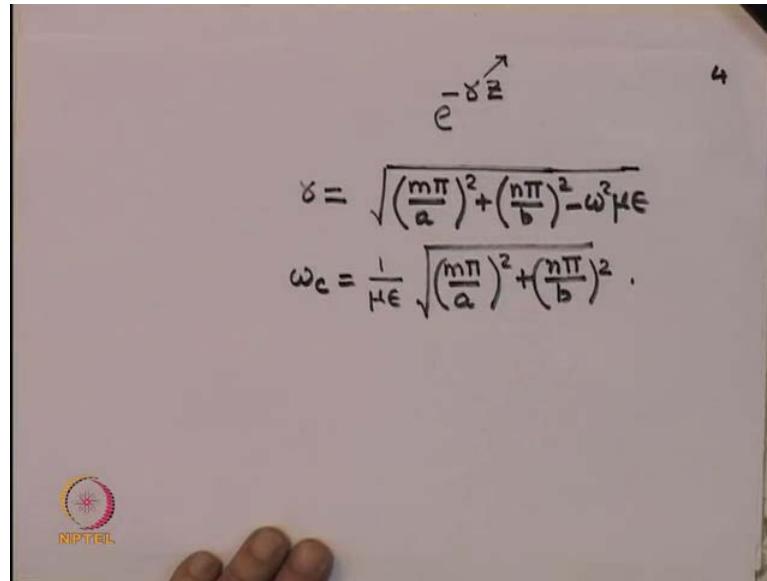

$$f_c = \frac{\omega_c}{2\pi} = \frac{1}{2\pi\sqrt{\mu\epsilon}} \sqrt{\left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2}$$

Minimum cutoff is for TE_{10} (or TE_{01}). It is called dominant mode. For this mode $E_x=0$

Prof. D K Ghosh, Department of Physics, IIT Bombay

So, as we have seen k square is this quantity and this is what it is. Now, if you look at γ now. γ is given by $m\pi$ by a whole square plus $m\pi$ by b whole square minus ω square μ ϵ . Now, this tells me now you remember that my propagation went as e to the power minus γz .

(Refer Slide Time: 22:11)

$$e^{-\gamma z}$$
$$\gamma = \sqrt{\left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2 - \omega^2 \mu \epsilon}$$
$$\omega_c = \frac{1}{\sqrt{\mu \epsilon}} \sqrt{\left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2}$$

And we have seen that gamma is given by root of m pi by a whole square plus n pi by b whole square minus omega square mu epsilon. Now, in order that this may be a propagating solution I want gamma to be imaginary. Otherwise it is an attenuating solution. Now, in order that gamma is imaginary it tells me there is a minimum frequency omega c given by well you want omega square mu epsilon to be greater than this. So, omega c is given by 1 over mu epsilon times square root of m pi by a whole square plus n pi by b whole square. And of course, so this if you like is my cut off frequency.

What I have written down here is the, this was of course, your angular frequency and this is the normal f c which is omega c by 2 pi. So, this is a minimum cut off, this is a cut off frequency for T E M n mode. Now, notice that if you take for instance T E 1 0 mode. So, m is equal to 1 n is equal to 0 and this depending upon which one you called to what, this is what is known as a dominant mode, because this is this is the mode for which the frequency is minimum whether it is T 1 0 or it could be T 0 1. It would depend upon which one of these dimensions is smaller or bigger and therefore, that is the cut off frequency.

(Refer Slide Time: 24:14)

ELECTROMAGNETIC THEORY

Rectangular waveguide – TM mode

$$E_z = E_z^0 \sin\left(\frac{m\pi}{a}x\right) \sin\left(\frac{n\pi}{b}y\right)$$

Neither m nor n can be zero, which implies a higher cutoff frequency than the lowest TE mode. TE mode is called the dominant mode

IIT Bombay

Prof. D K Ghosh, Department of Physics, IIT Bombay

And likewise you could work with E_z that is H_z equal to 0 transverse magnetic mode and E_z is not equal to 0 and if you did exactly the same algebra as we talked about earlier you find that for this TM mode E_z works out to be a product of sin into sin. Now, notice because this is product of two sin function unlike the TE mode which was the product of two cosine function, I cannot have m or n to be equal to 0 because if it is then E_z will be equal to 0. Now, I did not have that problem with the cosine function.

There all that I required is both m and n should not be 0 because if they were then that would be a constant, but in this case if either m or n becomes equal to 0 E_z vanishes and once E_z vanishes since H_z is equal to 0 all my components would trivially vanish. So, because of that the TM mode has a higher cut off frequency than that of TE mode and hence TE mode is known as the dominant mode.

(Refer Slide Time: 25:38)

ELECTROMAGNETIC THEORY

Rectangular waveguide - TE/TM mode

$$\beta = \sqrt{\omega^2 \mu \epsilon - \left(\frac{m\pi}{a}\right)^2 - \left(\frac{n\pi}{b}\right)^2} = \sqrt{\mu \epsilon [\omega^2 - \omega_c^2]}^{1/2}$$

$$\omega_c = \frac{1}{\sqrt{\mu \epsilon}} \sqrt{\left(\frac{m\pi}{a}\right)^2 + \left(\frac{n\pi}{b}\right)^2}$$

$$v_g = \frac{d\omega}{d\beta} = \frac{1}{\sqrt{\mu \epsilon}} \sqrt{1 - \frac{\omega_c^2}{\omega^2}}$$

$$v_\phi = \frac{\omega}{\beta} = \frac{1}{\sqrt{\mu \epsilon}} \frac{1}{\sqrt{1 - \frac{\omega_c^2}{\omega^2}}}$$

$$v_g v_\phi = \frac{1}{\mu \epsilon} \quad (\text{= } c^2 \text{ in vacuum})$$

Prof. D.K Ghosh, Department of Physics, IIT Bombay

So, let us look at the some minute properties. Supposing there is propagation. Again we are back to both it could this will be valid for both T E as well as T M mode. So, when there is a cut off when the frequency is above the cut off the propagation vector beta which is the same as i beta being equal to gamma is simply square root of omega square mu epsilon minus m pi by a whole square minus n pi by b whole square. And we define omega c as 1 over root of mu epsilon by into square root of this quantity. So, that beta can be written as root mu epsilon omega square minus omega c square raise to the power half and omega is greater than omega c for propagation in order that propagation may take place.

Now, if you have this. So, beta is your propagation vector. Now, remember that the group velocity of the wave is given by d omega by d beta where I have already seen what is the relationship between omega and beta which is gives me 1 over root mu epsilon. Incidentally this quantity is nothing but the velocity of light if it is in vacuum multiplied by 1 minus omega square by c square, but the phase velocity this of course, is less than the speed of light in vacuum as it ought to be. But the phase velocity if it is simply omega by beta is given by this expression namely c by square root of 1 minus omega c square omega square. Now, if you take the product of the group velocity with the phase velocity that gives you 1 over mu epsilon. And if you are dealing with vacuum between the plates then it is just equal to c square.

(Refer Slide Time: 27:35)

The slide displays the following equations:

$$\frac{E_x}{H_y} = \frac{i\omega\mu}{\gamma} = \frac{\omega\mu}{\beta} = \frac{\omega\mu}{\sqrt{\mu\epsilon}} \left[1 - \frac{\omega_c^2}{\omega^2} \right]^{-1/2} \equiv \eta_{TE}$$
$$\frac{E_y}{H_x} = -\eta_{TE}$$

The slide also features the NIPTE logo and the text 'Prof. D K Ghosh, Department of Physics, IIT Bombay' at the bottom.

Notice, one thing that in case of a T E mode if you took the ratio of E x to H y, if you recall when we talked about the propagation of uniform waves in free space we had seen the ratio of E x to H y was nothing but what we called as the characteristic impedance. Now, here also something very similar works out E x by H y is i omega mu by gamma and we have seen gamma is i beta. So, it is omega mu by beta and by substituting for beta you get this is equal to omega mu by root mu epsilon into this factor here. And this is what you denote as eta T E which means it is the characteristic impedance corresponding to the T E mode. So, E x by H y works out to eta T E and because of the directions E y by H x also works out in magnitude be eta T E, but this is given by minus eta T E.

(Refer Slide Time: 28:46)

ELECTROMAGNETIC THEORY

Power Transmission- TE mode

$$\langle S \rangle = \frac{1}{2} \text{Re} [E \times H^*] = \frac{1}{2} \text{Re} [E_x H_y^* - E_y H_x^*]$$

$$= \frac{|E_x|^2 + |E_y|^2}{2\eta}$$

$$P_{ave} = \int \langle S \rangle dx dy = \int_{x=0}^a \int_{y=0}^b \frac{|E_x|^2 + |E_y|^2}{2\eta} dx dy$$

For a lossy waveguide $P_{ave} \propto e^{-2\alpha z}$

Prof. D.K. Ghosh, Department of Physics, IIT Bombay

Now, let us look at the power transmission amount. So, we have seen that what we are looking for is transmission of power which is designated by the pointing vector. Pointing vector in terms of complex electric and real field magnetic field is given by half of real part of E cross H star. And just now we have seen that E x and H y's are related by this eta factor. Therefore, I can write the H as or E so here what I have got E cross H star real part and you remember I am in TE mode. So, my z component is 0. So, as a result the remaining components are given by E x H y star minus E y H x star.

What I have not written here is that because the direction of propagation is along the z direction. So, I have essentially taken the z component of E cross H star and if you now write down that H y by E x is eta, eta TE. So, you get E x square plus E y square divided by 2 eta. So, this is my average pointing vector. And the power that is transmitted is since the z direction is the direction of propagation it flows through at any point of time through x y plane. Therefore, you have to take the pointing vector and average pointing vector and integrate it from dx dy x going from 0 to a and y going from 0 to b. And if you do that this is the expression because you have to substitute the expressions for E x and E y and do this integration.

Supposing, we had a lossy wave guide. Now, if you had a lossy waveguide then we have seen that gamma will not become imaginary. But gamma will become real and by designating its real part as alpha, we get this quantity to be proportional because there is

an E and there is an H to e to the power minus 2 alpha z. So, that is the rate at which the power would attenuate. We will come back to this point a little later.

(Refer Slide Time: 31:12)

The slide displays the following equation for the average power transmission $\langle P \rangle$ in TE modes:

$$\langle P \rangle = \frac{|C|^2 \omega^2 \mu^2}{2\eta k^4} \left[\frac{n^2 \pi^2}{b^2} \int_0^a dx \int_0^b dy \cos^2\left(\frac{m\pi}{a}x\right) \sin^2\left(\frac{n\pi}{b}y\right) + \frac{m^2 \pi^2}{a^2} \int_0^a dx \int_0^b dy \sin^2\left(\frac{m\pi}{a}x\right) \cos^2\left(\frac{n\pi}{b}y\right) \right]$$

$$= \frac{|C|^2 \omega^2 \mu^2}{2\eta k^4} \left[\frac{n^2 \pi^2 ab}{b^2 \cdot 4} + \frac{m^2 \pi^2 ab}{a^2 \cdot 4} \right]$$

The slide also includes the NIPTE logo and the text: Prof. D.K Ghosh, Department of Physics, IIT Bombay.

So, if you look at what we said just now the power transmission is given by this expression, the you have to these are the two terms and you can do this integrations because they are fairly straight forward cosine square and sin square terms. Just if you do the integration each one on them will give you a by this will give you a by 2 this will give you b by 2. Therefore, this is the way they will work out. So, this is the expression for the power transmission. Having talked about rectangular parallelepiped wave guide I am going to now close the remaining sides as well. That is what I have got is what is known as a rectangular cavity.

So, I have got electromagnetic waves which are confined within the boundaries of a rectangular parallelepiped, I have taken the dimensions to be a b and d. I have not taken a b and c because c is the velocity of light, I do not want any confusion. So, I have taken this is what is known as a resonating cavity the, this is very similar to for example, like an L C circuit. We will see just as L C circuit is used to store electrical energy. A resonating cavity is used to store electromagnetic energy the typical resonating circuits however have a great advantage over the L C circuits because these have frequencies upward of a few hundred mega hertz.

(Refer Slide Time: 33:01)

ELECTROMAGNETIC THEORY

Resonating Cavity
Like LC circuits, resonating cavities can store electromagnetic energy.

1. Typical resonant circuits have frequencies upward of a few hundred MHz.
2. They are less lossy than LC circuits

NIPTEIL
Prof. D K Ghosh, Department of Physics, IIT Bombay

And they turn out to be less lossy than L C circuit. Now, remember when we talked about the parallelepiped rectangular waveguides we had not talked about losses at all, but we know that losses are facts of life. So therefore, we have to worry about losses you can minimize it, but we will be talking about it as we go along. The the technique of discussing the resonant cavity is very similar to what we did. So, let us first look at the wave equation.

(Refer Slide Time: 33:44)

5

$$\nabla^2 E_d = -\omega^2 \mu \epsilon E_d$$
$$E_d = X_d(x) Y_d(y) Z_d(z)$$
$$YZ \frac{\partial^2 X_d}{\partial x^2} + XZ \frac{\partial^2 Y_d}{\partial y^2} + XY \frac{\partial^2 Z_d}{\partial z^2} = -\omega^2 \mu \epsilon . XYZ$$
$$\frac{1}{X} \frac{\partial^2 X}{\partial x^2} + \frac{1}{Y} \frac{\partial^2 Y}{\partial y^2} + \frac{1}{Z} \frac{\partial^2 Z}{\partial z^2} = -\omega^2 \mu \epsilon$$
$$\frac{\partial^2 X}{\partial x^2} = -k_x^2 X; \quad \frac{\partial^2 Y}{\partial y^2} = -k_y^2 Y$$
$$\frac{\partial^2 Z}{\partial z^2} = -k_z^2 Z \quad : \quad k_x^2 + k_y^2 + k_z^2 = \omega^2 \mu \epsilon$$

NIPTEIL

Remember, we had said $\nabla^2 E$ any component E_x , E_y or E_z is given by $-\omega^2 \mu \epsilon E$. So, what you do is this. Now, this is the equation which you need to solve ∇^2 is $\frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2}$. Now, I will use the same technique namely the technique of separation of variable by assuming that this E_x remember my E_x can be $X Y Z$ component whichever fancy me. This is written as a product of capital X which is a function of x only, capital Y which is a function of y only and capital Z which is a function of z only.

And what I do is exactly what we did earlier so if you write down this is $\frac{d^2}{dx^2} E_x = X Y Z$. So, this gives me X of x multiplied by $Y Z$ plus $\frac{d^2}{dy^2} E_x = Y X Z$ plus $\frac{d^2}{dz^2} E_x = Z X Y$. This is equal to $-\omega^2 \mu \epsilon X Y Z$. So, if you divide this equation all through by $X Y Z$ you will find this thing that $\frac{1}{X} \frac{d^2 X}{dx^2} + \frac{1}{Y} \frac{d^2 Y}{dy^2} + \frac{1}{Z} \frac{d^2 Z}{dz^2} = -\omega^2 \mu \epsilon$. So, what we do is this. Now, we we exactly work the same way as we did earlier.

This is a function of X only, this is a function of Y only, this is a function of Z only. These three things must be added in such a way that for all values of X , Y and Z it must give me a constant. Now, obviously that is a tall order unless this is the constant, this is a constant and this is a constant and these three constants added together gives me the third constant. Now, so what I require is $\frac{d^2 X}{dx^2} = -k_x X$ that is equal to a constant. So, let me write it as $-\frac{d^2 X}{dx^2} = k_x X$, then $\frac{d^2 Y}{dy^2} = -k_y Y$, $\frac{d^2 Z}{dz^2} = -k_z Z$.

So, if I do that this term becomes $-\frac{d^2 X}{dx^2}$, this term becomes $-\frac{d^2 Y}{dy^2}$, this term becomes $-\frac{d^2 Z}{dz^2}$ so that this equation will be satisfied if I have $k_x X^2 + k_y Y^2 + k_z Z^2 = \omega^2 \mu \epsilon$. This is the technique of separation of variable. The advantage is if you look at any one of these equations, these are equations which are known to us in solution of simple harmonic motion.

(Refer Slide Time: 38:15)

ELECTROMAGNETIC THEORY

Resonating Cavity

$$E_x(x, y, z) = [A_x \cos k_x x + B_x \sin k_x x] [C_x \cos k_y y + D_x \sin k_y y] \times [E_x \cos k_z z + F_x \sin k_z z]$$

$E_x(x, y, z) = 0$ for $y = 0$, for $y = b$, for $z = 0$ and for $z = d$

$$E_x(x, y, z) = E_x^0 [A_x \cos k_x x + B_x \sin k_x x] \sin k_y y \sin k_z z$$

$$k_y = \frac{m\pi}{b}; k_z = \frac{n\pi}{d}; \quad m = \pm 1, \pm 2, \dots; n = \pm 1, \pm 2, \dots$$

 Prof. D.K Ghosh, Department of Physics, IIT Bombay

So, that they all give me linear combination of the sum of x and $\cos k_x x + \sin k_x x$ etcetera that is supposing I am writing E_x . So, I have got this term which is my capital X which is $A_x \cos k_x x$ and $B_x \sin k_x x$ and similarly y and similarly z . Now, what you do from here? The, what I do now is this. I now know that I have a rectangular parallelepiped. Therefore, my x component for instance will be equal to 0 either when y is 0 or d because that is one plane on which my x component of x direction is the tangential direction or z is equal to 0 and z is equal to d . So, E_x of x, y, z let me illustrate this here is equal to 0 for y is equal to 0 y is equal to b z is equal to 0 and z is equal to d .

Now, look at what it means. If I want this quantity to be equal to 0 for y is equal to 0. Now, substitute y is equal to 0 here. So, this term automatically goes away, this term automatically goes away and I am left with $A_x \cos k_x x$ so $C_x \cos k_y y$ remains. Now, the, so this term will become 0 and I will have $C_x \cos k_y y$. Now, I want that to be 0 for all values, all for y is equal to b as well. Now, if I do that then that tells me that my k_y must take values $m\pi$ by b because then only this term become equal to 0. I cannot have both C_x is equal to 0, D_x is equal to 0 simultaneously.

Because if I did it then the entire E_x will go away and likewise you substitute that this field must become equal to 0 for z is equal to 0 which will make this this term go away. As a result my E_x term must be equal to 0 and then for z is equal to d . So, if

you put that then I get E alpha this term remains and from these two only the sin k y y and sin k z z remains and the factor D alpha into F alpha, I have combined it into one constant which is E x 0. So, this is my structure of E x with m becoming equal to plus minus 1 plus minus 2 etcetera, etcetera. So, that is the E x x.

(Refer Slide Time: 41:05)

ELECTROMAGNETIC THEORY

Resonating Cavity

$$E_y(x, y, z) = E_y^0 [C_y \cos k_y y + D_y \sin k_y y] \sin k_x x \sin k_z z$$

$$k_x = \frac{l\pi}{a}; k_z = \frac{n\pi}{d}; \quad l = \pm 1, \pm 2, \dots; n = \pm 1, \pm 2, \dots$$

$$E_z(x, y, z) = E_z^0 [E_z \cos k_z z + F_z \sin k_z z] \sin k_x x \sin k_y y$$

$$k_x = \frac{l\pi}{a}; k_y = \frac{m\pi}{b}; \quad l = \pm 1, \pm 2, \dots; m = \pm 1, \pm 2, \dots$$

 Prof. D K Ghosh, Department of Physics, IIT Bombay

Now, likewise I go to E y and well the argument is essentially the same. The just as you got when you add E x you got sin k y y and sin k z z and the x part had both the terms. Here, also I will get since it is E y the y part will have cosine and sin, the x parts will have only sins and k x will be l pi by a k z will be equal to n pi by d and likewise for E z as well.

(Refer Slide Time: 41:41)

ELECTROMAGNETIC THEORY

Resonating Cavity

$$\vec{\nabla} \cdot \vec{E} = 0 \Rightarrow$$

$$E_x^0 k_x [-A_x \sin k_x x + B_x \cos k_x x] \sin k_y y \sin k_z z$$

$$+ E_y^0 k_y [-C_y \sin k_y y + D_y \cos k_y y] \sin k_x x \sin k_z z$$

$$+ E_z^0 k_z [-E_z \sin k_z z + F_z \cos k_z z] \sin k_x x \sin k_y y = 0$$

This equation must be satisfied at all points inside the cavity.

 Prof. D.K Ghosh, Department of Physics, IIT Bombay

Now, how do you proceed from here? Now, notice that irrespective of my solutions my $\text{div } \vec{E}$ must be equal to 0. $\text{div } \vec{E}$ is $\frac{d}{dx} E_x + \frac{d}{dy} E_y + \frac{d}{dz} E_z$. Since, I have already obtained E_x , E_y and E_z what I require is that simply differentiate. So, when you differentiate $\cos k_x x$ you get minus $A_x \sin k_x x$. $\sin k_x x$ give me B_x . So, this is what you get, this is first term is obtained by differentiating with respect to x , the second term differentiating with respect to y , the third term differentiating with respect to z .

Now, unlike E which must be equal to 0 the tangential component must be equal to 0 at the boundaries my $\text{div } \vec{E}$ must be equal to 0 anywhere, for any value of x, y, z my $\text{div } \vec{E}$ must be equal to 0. Now, so what you do is for instance look at this equation. Try to satisfy this $\text{div } \vec{E} = 0$ at for instance try to satisfy it at $x = 0$. Now, if your $x = 0$ let me first dispose off the last two terms. If $x = 0$ these two terms go away. Remember, I have said this relationship is valid at all values of x, y, z in particular for $x = 0$ and whatever y, z you prefer. So, when I put $x = 0$ these two terms go away, but if I put $x = 0$ I have left with $B_x \cos k_x x \sin k_y y \sin k_z z$, $\frac{d}{dx}$ is a constant which can come here.

(Refer Slide Time: 43:36)

ELECTROMAGNETIC THEORY

Resonating Cavity

Satisfy at $(x=0,y,z) \Rightarrow B_x=0$; at $(x,y=0,z) \Rightarrow D_y=0$;
at $(x,y,z=0) \Rightarrow F_z=0$

$$\vec{E} = \hat{i}E_x^0 \cos(k_x x) \sin(k_y y) \sin(k_z z) + \hat{j}E_y^0 \sin(k_x x) \cos(k_y y) \sin(k_z z) + \hat{k}E_z^0 \sin(k_x x) \sin(k_y y) \cos(k_z z)$$

$$k_x = \frac{l\pi}{a}; k_y = \frac{m\pi}{b}; k_z = \frac{n\pi}{d}$$

l, m, n are integers, which cannot all be zero simultaneously.

Prof. D K Ghosh, Department of Physics, IIT Bombay

So, this is what I am left with. Now, identically what you do is this for example, so that get me a D_y equal to 0 and you can again do this for y is equal to 0 x and z arbitrary, z is equal to 0 x and y arbitrary. If you do that one by one, one of these terms constants will go away and you will be left with terms of this type x component $\cos k_x x$, the two others are $\sin y$ components $\cos k_y y$, the two other things are $\sin z$ components $\cos k_z z$, two other things are \sin and k_x is $l\pi$ by a k_y is $m\pi$ by b k_z is $n\pi$ by d . Notice that I cannot have l, m and n becoming simultaneously 0 that is not permitted because if I did then this E will trivially go out it could become 0.

Because at x equal to b for example, y equal to b this will make $\sin k_y y$ equal to 0. So, these integers cannot be simultaneously 0. So, I write down $\text{div } \vec{E}$ is equal to 0 since all of them are of \sin because this is my E . So, when I do $\text{div } \vec{E}$ I get d by $d x$ will give me a \sin .

(Refer Slide Time: 45:06)

ELECTROMAGNETIC THEORY

Resonating Cavity

$$\vec{\nabla} \cdot \vec{E} = 0 \Rightarrow (E_x^0 k_x + E_y^0 k_y + E_z^0 k_z) \sin(k_x x) \sin(k_y y) \sin(k_z z) = 0$$

has to be valid at all points in the cavity.

$$E_x^0 k_x + E_y^0 k_y + E_z^0 k_z = 0$$

$$\vec{E} \perp \vec{k}$$

$$\nabla^2 \vec{E} = -\omega^2 \mu \epsilon \Rightarrow k_x^2 + k_y^2 + k_z^2 = \omega^2 \mu \epsilon$$

$$\frac{l^2 \pi^2}{a^2} + \frac{m^2 \pi^2}{b^2} + \frac{n^2 \pi^2}{d^2} = \omega^2 \mu \epsilon = \frac{\omega^2}{c^2}$$

NIPTEIL

Prof. D K Ghosh, Department of Physics, IIT Bombay

So, this is the way it will be that all the sin are common. I get $E_x^0 k_x$, $E_y^0 k_y$, $E_z^0 k_z$ this is wrongly written. Now, this equation has to be valid for all values of x , y and z inside the cavity. As a result this tells me $E_x k_x$ plus $E_y k_y$ plus $E_z k_z$, this is to be corrected is equal to 0. So, let me write it down since that equation is slightly wrongly written.

(Refer Slide Time: 45:42)

6

$$E_x^0 k_x + E_y^0 k_y + E_z^0 k_z = 0$$

$$\vec{E} \perp \vec{k}$$

$$\nabla^2 \vec{E} = -\omega^2 \mu \epsilon$$

$$k_x^2 + k_y^2 + k_z^2 = \omega^2 \mu \epsilon$$

$$\frac{l^2 \pi^2}{a^2} + \frac{m^2 \pi^2}{b^2} + \frac{n^2 \pi^2}{d^2} = \frac{\omega^2}{c^2}$$

NIPTEIL

So, I must have $E_x^0 k_x$ plus $E_y^0 k_y$ plus $E_z^0 k_z$. Since, E_x , E_y , E_z 0s are E_x^0 , E_y^0 , E_z^0 zeroes or the magnitudes of the components of the electric vector, k_x , k_y and k_z

are component of the propagation vector. This equation simply tells me that the electric field direction is perpendicular to the direction of the propagation vector. Returning back to the wave equation at del square of E. So, del square is d square by d x square plus b square by d y square plus b square by d z square, this quantity is equal to minus omega square mu epsilon.

Remember, in each of the components take any component. I have to differentiate only the cosine part twice. So, I get k x square plus k y square plus k z square equal to omega square mu epsilon and of course, I know that k x is equal to l pi by a. So, this l square pi square by a square plus m square pi square by b square plus n square pi square by d square is equal to omega square supposing I am in vacuum then omega square by c square.

So, this is what I have got. Now, like we classified the waves in a rectangular waveguide or in a infinite semi infinite waveguide it is possible to talk about the classification in terms of T E and T M mode as well. Generally, conventionally the longer direction will be considered to be the propagation direction, but of course, it really is not particularly important here.

(Refer Slide Time: 48:09)

ELECTROMAGNETIC THEORY
Resonating Cavity
TE Modes TE_{lmn}

$$E_z = 0 \Rightarrow E_z \equiv 0 \Rightarrow E_x^0 k_x + E_y^0 k_y = 0$$

$$E_x = E_x^0 \cos(k_x x) \sin(k_y y) \sin(k_z z)$$

$$E_y = E_y^0 \sin(k_x x) \cos(k_y y) \sin(k_z z)$$

B fields can be obtained using Faraday's Law

NIPTIIL
 Prof. D K Ghosh, Department of Physics, IIT Bombay

So, if I take E z is equal to 0 which is my T E mode. So, the, I will label the modes by T E l m n. Now, let in this case since it is T E my E z is equal to 0 which implies that E z 0 is equal to 0 and this implies that E x 0 k x plus E y 0 k y is equal to 0. This is because E

dot k is equal to 0. So, I am left with now, E x and E y. So, E x I have written down. E x 0 cos k x x E y E 0 i 0 cos k y y, the other two components are sin.

(Refer Slide Time: 48:51)

ELECTROMAGNETIC THEORY
Resonating Cavity TE Modes
TE_{lmn}

$$H_x = \frac{1}{-i\omega\mu} \frac{-\partial E_y}{\partial z} = \frac{1}{i\omega\mu} E_y^0 k_z \sin(k_x x) \cos(k_y y) \cos(k_z z)$$

$$H_y = \frac{1}{-i\omega\mu} \frac{\partial E_x}{\partial z} = \frac{1}{-i\omega\mu} E_x^0 k_z \cos(k_x x) \sin(k_y y) \cos(k_z z)$$

$$H_z = \frac{1}{-i\omega\mu} \left(\frac{\partial E_y}{\partial x} - \frac{\partial E_x}{\partial y} \right) = \frac{1}{-i\omega\mu} (E_y^0 k_x - E_x^0 k_y) \cos(k_x x) \cos(k_y y) \sin(k_z z)$$

 Prof. D K Ghosh, Department of Physics, IIT Bombay

And you can now determine the corresponding H components, the components of the magnetic field H x. This is once your E z is 0 you can write them down and these are the expressions for the H x H y and H z. So, this is fairly standard just a differentiation and you can just look at it and work it out yourself.

(Refer Slide Time: 49:35)

$(TE)_{101}$ $l=1$
 $m=0$
 $n=1$

 7

Let me let me now specialize it to a particular mode supposing I am working out to the TE_{101} mode that is l is equal to 1, m is equal to 0 and n is equal to 1. Just going back a little bit you notice that if m is equal to 0 then by E_x becomes equal to 0. So, the only component of electric field that survives is E_y which will be given by $E_y = E_0 \sin k_x x$. This term is 1 and into $\sin k_z z$. So, I have written that down that you have got E_x is equal to 0. And normally it is conventional to write the TE_{101} mode in terms of the H_z that is the amplitude of H_z which is the one which determines the TE_{101} mode.

So, for example, H_z is this quantity here. So, this quantity here, remember k_y is equal to 0. So, this quantity here $E_y = E_0 \cos k_x x \sin k_z z$ by minus $i\omega\mu$ will be designated as $H_z = H_0 \cos k_x x \sin k_z z$, the y thing is not there. And using my standard equations relating the E_y and H_x to H_z I can write E_y and H_x like this, H_y which again has a proportional to $\sin k_y y$ is equal to 0 because k_y is equal to 0. So, this gives me the modes, the fields for 101 .

Now, the next thing that we need to do is to find out an expression for the loss in case of the resonating waveguides. This is called resonating because you notice that because of this relationship that we had that $\omega^2 \mu \epsilon$ is given by this. The ω of that are permitted, are very specified frequencies. See, in the rectangular parallelepiped wave guides that we had where z direction was the direction of propagation, we had seen that there was a minimum frequency about which the propagation took took place.

In this case however there are specified frequencies at which the propagation will take place depending upon the mode that we have got, because $\omega^2 \mu \epsilon$ is $1 + \frac{\pi^2 a^2}{4} + \frac{\pi^2 m^2 b^2}{4} + \frac{\pi^2 n^2 d^2}{4}$. And once you are fixed l m and n the ω can take only specified values. Because of that we call it resonating modes, because unlike the other two wave guides that we have talked about in this case there is no cut off frequency above which the propagation takes place, there are frequencies at which the propagation takes place.

So, let us look at this. So, as I said in the beginning the purpose of a resonating cavity is to provide a mechanism for storing electromagnetic energy. However, in principle though we have said that my walls are perfectly conducting the there would be losses in

the dielectric. So, with every cycle by cycle I mean supposing my z direction is taken as a propagation direction. So, my wave would proceed towards z is equal to d come back to z is equal to 0. So, with every cycle a certain amount of loss will be there. Now, what I will do is this. I define the quality factor which is also known as the q factor of a cavity as the ratio of the energy that is stored in the cavity to the amount of energy that is lost through the walls of the cavity, every cycle. So, that is that is defined as the q.

(Refer Slide Time: 54:47)

The slide displays the following equations for the average energy stored in a TE₁₀₁ cavity:

$$\begin{aligned} \langle W \rangle &= \frac{\epsilon}{2} \int_{vol.} |E|^2 dV = \frac{\epsilon}{2} \int_{vol.} |E_y|^2 dV \\ &= \frac{\epsilon \omega^2 \mu^2 a^2}{2 \pi^2} |H_z^0|^2 \int_0^a dx \int_0^b dy \int_0^d dz \sin^2(k_x x) \sin^2(k_z z) \\ &= \frac{\epsilon \omega^2 \mu^2 a^3 b d}{8 \pi^2} |H_z^0|^2 \end{aligned}$$

The slide also features the IIT Bombay logo and the text 'Prof. D K Ghosh, Department of Physics, IIT Bombay' at the bottom.

Now, how do I calculate this q? I will just begin the calculation today and we will try to complete it next time.

ELECTROMAGNETIC THEORY

Mode Losses in a cavity

$$Q = \frac{\text{Energy Stored in the cavity}}{\text{Energy lost per cycle through the walls of the cavity}}$$

 Prof. D K Ghosh, Department of Physics, IIT Bombay

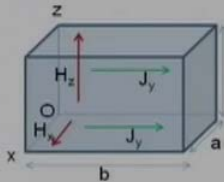

So, first is you notice the numerator. The numerator is the amount of energy that is stored in the cavity. Now, we had seen that the average energy that is stored in a electromagnetic field is given by $\epsilon_0 \langle E^2 \rangle$, there is an additional $\frac{1}{2}$ has come in because of my time factor that $\sin^2 \omega t \cos^2 \omega t$ average. So, it is $\epsilon_0 \int \langle E^2 \rangle dV$. Now, I am in T E mode, E_z is equal to 0, E_x was automatically equal to 0.

Therefore, I have got simply E_y^2 to take care of, if you put in the expression for E_y^2 which is written in terms of H_z you will notice that E_y is product of $\sin k_x x$ and $\sin k_z z$. So, I have got $\sin^2 k_x x \sin^2 k_z z$. So, the dy integration give me ab . And integrations you can easily do by writing \sin^2 in terms of $\cos 2\theta$ $\sin^2 \theta$ in terms of $\cos 2\theta$ and integrating this out. Now, if you integrate that out you get the amount of energy that is stored to be given by this.

ELECTROMAGNETIC THEORY

Resonating Cavity: surface currents

$$\vec{J}_s = \hat{n} \times \vec{H}_t$$

Front & Back surfaces : $\hat{n} = \pm \hat{x}; x = 0, a$

$$\vec{J}_s = (\pm \hat{x}) \times (H_y \hat{y} + H_z \hat{z}) = \mp H_z \hat{y}$$

$$|\vec{J}_s|^2 = |H_z^0|^2 \sin^2 k_z z$$

The next question is what does one do to calculate the amount of loss. So, first thing that we realize is the losses must take place through the walls of the cavity. Now, I assume that the walls are made of good conductors. Now, if the walls are made of good conductors then the skin depth that is the depth to which the fields penetrate will be small, the skin depth is low. Now, if this skin depth is small I can assume the field in these is the same as the field on the surfaces of these conductors, conducting boundaries.

So, I also know that if I have the tangential component of the magnetic field that gives me a surface current. It is this surface current which I will need to calculate on each of the six phases. And once I know what is the resistance of each one of these phases, I simply calculate how much is the joule loss on each of these phases. This is a calculation which I will leave for the next lecture.
