Representation on Function Spaces - I

(Refer Slide Time: 00:20)

To recapitulate; we showed that there is this algebra of the J_i J_j equal to $i \epsilon_{ijk} J_k$; where if J are equal to i times L then we have $SO(3)$ group and 3×3 matrices and if say J_i . Now we will pretend as if J_i can be either of the two, if J_i are equal to one-half times the τ_i or Pauli matrices then this serves $SU(2)$ algebra, but these are 2×2 complex and these are 3×3 real in the form of L , but you can see because there is an overall multiplication of i it is really a real representation; whereas this is intrinsically complex you cannot make all the 3 τ matrices real.

If τ_3 and τ_1 are real $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$; then the τ_2 is necessarily $\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$. So, that they all remain Hermitian and that is how we get unitary matrices because intrinsic complex nature of τ which ensure that $\tau_i^\dagger = \tau_i$. If you somehow try to make τ_2 matrix real by pulling out an i from it; you can have all 3 real, but then you will have this i will get messed up and they will not remain all Hermitian, but only if you do the standard choice these are Hermitian and gives obvious unitary matrix; under exponentiation.

So, when you exponentiate a Hermitian matrix with an i in front of it you automatically get a unitary matrix. So, that ensures all that and so that is a good convention to use and this is the standard one. Now next way so we saw that topology that the $SU(2)$ is a double cover and all that; now we will see the representations. So, for representations we started with the J_+ and J_- construction and who remembers this is equal to plus minus sorry J_+ and J_- is just 2 times J_z I think, but the sign is I hope correct, we can do a little rough work on this side. So, $J_x \pm i J_y$ comma $J_x \mp i J_y$ right; we will have $J_x \mp i J_y$ times $J_x \pm i J_y$ and plus the other one and that is $J_x J_y$ is equal to $i J_z$. So, with this it gives plus J_z . So, this is just equal to 2 times J_z and we had that J_+ plus minus sorry J_z acting on J_+ plus minus. I am calling acting on because actually if you write it in this order $J_z J_+$ plus minus then it is easy to see what happens to the state; I will show it again.

So, this I think we found to be equal to plus minus J_+ plus minus and as a result we find that; thus if J_z acting on m is equal to m times J_z .

(Refer Slide Time: 05:12)

$[J_x + iJ_y, J_x - iJ_y]$
 $[J_z, J_{\pm}] = \pm J_{\pm}$
 Thus if $J_z |m\rangle = m |m\rangle$
 $J_z (J_{\pm} |m\rangle) = (J_z J_{\pm} - J_{\pm} J_z + J_{\pm} J_z) |m\rangle$
 $= ([J_z, J_{\pm}] + J_{\pm} J_z) |m\rangle$
 $= (\pm J_{\pm} + J_z |m\rangle)$
 $= (\pm 1 + m) (J_{\pm} |m\rangle)$
 Next consider
 $J_+ J_- + J_- J_+ = (J_x + iJ_y)(J_x - iJ_y) + (J_x - iJ_y)(J_x + iJ_y)$

So, we choose the basis to be Eigen values of J_z then what happens with application of J_+ plus or minus on m . So, suppose m is an Eigen state of this J_z . So, if we apply J_+ plus minus to one of these Eigen values of J_z and then check again what; it has done to the Eigen value. So we query what is the effect of J_z if I take an old Eigen value, but hitted with J_+ plus minus; then we can rewrite this is equal to $J_z J_+$ plus minus J_+ plus minus J_z and plus J_+ plus minus J_z acting on m , but that becomes equal to; so this is just adding

and subtracting and that becomes equal to the commutator $J_z J_+ - J_+ J_z$ plus minus and plus $J_+ J_z - J_z J_+$ but that is just m times m so sorry; so I should write like this first and then that becomes because J_z commutator is this plus minus J_z that becomes equal to plus minus $J_+ J_z - J_z J_+$ and m I have to put here thank you and plus $J_+ J_z - J_z J_+$ times m on m . So, I get back m plus minus 1; 1 plus m $J_+ J_z - J_z J_+$. So, the Eigen value m is augmented or reduced by one by application of this $J_+ J_z - J_z J_+$.

Now to prove the next things we need to use some tricks and the trick is that if you take; consider the product $J_+ J_- + J_- J_+$ plus $J_- J_+ + J_+ J_-$ ok. Now, this is equal to $J_x^2 + J_y^2$ plus i $J_y J_x - J_x J_y$ plus $J_x^2 + J_y^2$ minus i $J_y J_x - J_x J_y$ plus i $J_y J_x - J_x J_y$.

(Refer Slide Time: 08:29)

Next consider

$$J_+ J_- + J_- J_+ = (J_x + iJ_y)(J_x - iJ_y) + (J_x - iJ_y)(J_x + iJ_y)$$

$$= J_x^2 + J_y^2 + i[J_y, J_x] + J_x^2 + J_y^2 - i[J_y, J_x]$$

$$= 2(J_x^2 + J_y^2)$$

Next note $J_+ = J_-^\dagger = (J_x - iJ_y)^\dagger = J_x + iJ_y$ ✓

Thus $J_+ J_- + J_- J_+$ is of the form $Z_1 Z_1^* + Z_2 Z_2^* \geq 0$

is a positive definite operator in the sense that every eigenvalue is non-negative.

PHSAPL / SBC

So, it becomes equal to J_x^2 then here it becomes equal to plus J_y^2 and then we get a cross term which is equal to i times $J_y J_x - J_x J_y$. So, we get the $J_y J_x - J_x J_y$ commutator and then from the second term we get again J_x^2 plus J_y^2 , but this time we get minus i times the $J_y J_x - J_x J_y$ commutator; sorry there was an sorry J_x plus i J_y right.

So, yes so we got J_x^2 plus J_y^2 which is equal to so these terms cancel and we got J_x^2 plus J_y^2 twice. So, we can write it as equal to 2 times the whole of J^2 , but minus J_z^2 ; because $J_x^2 + J_y^2 + J_z^2 = J^2$ and minus J_z^2 . So, the this 2 times $J_x^2 + J_y^2$ is just 2 times this, but now we know that J^2 commutes with all the J_x , J_y and J_z . So, J^2 is

a number it is a time something times identity and J_z in our basis the J_z is also a number.

So, we get these numbers for J^2 and J_z . So, next note that J_+ is equal to $J_-^\dagger$ because this is $J_x - iJ_y$ J_- is $J_x + iJ_y$; if I dagger it I get $J_x - iJ_y$, but which is J_+ and then plus i times J_y dagger, but which is J_y ok. So, $J_+ J_-$ plus is just $J_- J_+$ therefore, this left hand side $J_+ J_- + J_- J_+$ is a positive definite operator you are taking operator time it is own Hermitian conjugate operator time it is own Hermitian conjugate; is of the form $\langle z | z \rangle + \langle z | z \rangle$ i.e. greater than or equal to 0.

So, although they are operators; you know they are they are if you represent them as matrices then they will follow this same rule that if you take matrix and it is own dagger then all it is Eigen values will be positive. So, this is positive operator; in the sense that all it is Eigen values are positive your positive definite.

(Refer Slide Time: 13:03)

Next note $J_+ = J_-^\dagger = (J_x - iJ_y)^\dagger = J_x + iJ_y$ ✓

Thus $J_+ J_- + J_- J_+$ is of the form $z_1 z_1^* + z_2 z_2^* \geq 0$

This is a positive definite operator in the sense that every eigenvalue is positive definite

Thus any state $|m\rangle$,

$$2\langle m | J^2 - J_z^2 | m \rangle = 2(J^2 - m^2) \langle m | m \rangle = \langle m | J_+ J_- + J_- J_+ | m \rangle \geq 0$$

Thus $(J^2 - m^2) \geq 0$

Logos: CDEEP IIT Bombay, NPTEL

So, this is getting to be a slightly boring proof, but I will just go through it because actually you will probably do it in quantum mechanics class. I was about to skip it last time, but then I taught I may as well finish the argument. So, we are now observing that I have a positive definite operator and this side are things that become numbers thus on any state m ; we would find that 2 times m J^2 minus J_z^2 m which should be

equal to 2 times and let us call this for the time being J^2 I think we will just call it J^2 squared you know where it is some number.

J^2 minus m^2 and then there is basically m . So, it is the norm of a state m and this is equal to $m J^2$ plus J^2 minus J^2 plus m , but which must be greater than or equal to 0; because this is just calculating the expectation value of this positive definite operator. So, it means that J^2 without any arrow I have not put any arrow because that is the now it has become a number; the vectorial operator any way it was vector in the sense of having J_x^2 plus J_y^2 plus J_z^2 all the squared operators become numbers.

So, the whole number we are generically calling J^2 minus m^2 is greater than or equal to 0. Now we had seen so this is as sort of long winded proof and you have to spend some time reading it again. Now we are already proved that this m are raised and lowered by plus or minus 1. Our first statement here, but we also learn that the J^2 which is a fix number it does not change with m because it commutes with all the operators. So, it is it is a something times identity.

So, J^2 is a fix number for all the states related by J^2 plus J^2 minus. So, m cannot increase indefinitely and this was our proof that you cannot there is an upper bound on how much m can go.

(Refer Slide Time: 16:04)

$J^2 = J_x^2 + J_y^2 + J_z^2$
 Thus we learn that
 $m \xrightarrow{J_{\pm}} m \pm 1$ but can not do so indefinitely
 because " J^2 " is fixed for all such states raised / lowered by $J_{\pm}$ and
 $J^2 - m^2 \geq 0$
 Thus there must be some $|l\rangle$ s.t.
 $J_+ |l\rangle = 0$

 CDEEP
 IIT Bombay

 NPTEL

So, our claim now is that m goes to m plus minus 1, but cannot do so indefinitely under J plus minus goes to m plus minus, but cannot do so indefinitely; because there is an upper bound. So, because J square is fixed; for all such states raised and lowered by J plus minus and we learn that J square minus m square is greater than or equal to 0.

So, this is the reasoning for why m as to be kept so thus there must be some l such that J_z can sorry J plus very sorry J plus cannot raise it any further. It has to make it 0 otherwise it will keep going indefinitely; so there must exist a highest weight state. Now next we need a sub identity of this; here we directly calculated all this, but there is so yeah actually we can see from here. Now note so actually I do not know how to punctuate it; it is like step 1, step 2 if it was a mathematics book they would have called it lemma 1, lemma 2, lemma 3.

(Refer Slide Time: 18:23)

$L_1^2 + L_2^2 \geq 0$
 This is a positive definite operator in the sense that every eigenvalue is positive definite
 Thus any state $|m\rangle$,
 $2\langle m | \vec{J}^2 - J_z^2 | m \rangle = 2(J^2 - m^2)\langle m | m \rangle$
 $= \langle m | J_+ J_- + J_- J_+ | m \rangle \geq 0$
 Thus $(J^2 - m^2) \geq 0$
 Next, recall $J_- J_+ = J_x^2 + J_y^2 - J_z^2$ (from pg 3)
 Thus $0 = J_- J_+ |l\rangle = (J^2 - J_z^2 - J_z) |l\rangle$
 $J^2 = L^2 + L \quad \therefore J_z |l\rangle = l |l\rangle$

But so next recall what this J plus J minus multiply multiplied out was giving this and we added to J minus J plus which we separately calculated, but suppose we you will drop the second line and second term then recall that actually which one do I need? I need J minus J plus. So, look at actually drop the first term and first line and look at the second one; recall J minus J plus is equal to the second line and then minus i times $J_y J_x$. $J_y J_x$ is minus of $J_x J_y$; so that removes this minus sign, but then that becomes equal to $i J_z$. So, i times that i becomes a minus. So, it become minus times J_z .

So, the $J_- J_+ |l\rangle$ is equal to $J_x^2 + J_y^2$; so this is from page 3. Now we go back to this statement and see that, thus 0 equal to you know $J_+ |l\rangle$ is equal to 0 , but I can now hit it with a J_- in front and nothing will change right because $J_+ |l\rangle$ was 0 . So, I multiply by J_- on the left it is still 0 , but then that is equal to this and this is equal to what? My J^2 and minus J_z^2 minus J_z .

So, if the highest value is equal to l ; thus I find that J^2 value is equal to l^2 plus l because l is the Eigen value of J_z . So, we may as well retain it on this side acting on l . So, $J_+ J_- |l\rangle$ acting on l is same as the combined operator J^2 minus the known operator acting on l , but these have a Eigen value l on the state l whatever l is we do not know it right now it is whatever the highest value of m is, but the J^2 value gets fixed to be equal to that value. Highest value squared l into l^2 plus l this is of course, a famous result which everybody knows l into $l + 1$.

So, since we already know that this is greater than or equal to 0 ; we also know that there is a lower bound. So, m cannot decrease indefinitely because this is an m^2 . So, m cannot be going negative indefinitely. So, there is some lowest lower bound also.

(Refer Slide Time: 22:07)

So, continuing; if the lowest Eigen value of J_z is l' something else. Then we know that $J_- |l'\rangle$ must be equal to 0 but that implies that $J_+ J_- |l'\rangle$ equal to 0 equal to and now we play the same trick instead of writing here on the highest weight we have to apply J_+ to get 0 and the lowest weight or lowest Eigen

value we have to apply the J minus and then J plus; so we look back and find out what was J plus J minus only the sign was sign changes of this sign.

(Refer Slide Time: 23:20)

The slide shows the following handwritten derivations:

$$\text{Thus } (J^2 - m^2) \geq 0$$

$$\text{Thus } 0 = J_- J_+ |l\rangle = (J^2 - J_z^2 - J_z) |l\rangle$$

$$\text{Thus, } \boxed{J^2 = L^2 + L} \quad \because J_z |l\rangle = l |l\rangle$$

$$J_- |l'\rangle = 0$$

$$\Rightarrow J_+ J_- |l'\rangle = 0 = (J_x^2 + J_y^2 + J_z^2) |l'\rangle$$

$$= (J^2 - J_z^2 + J_z) |l'\rangle$$

$$\Rightarrow J^2 = l(l+1) = (l'^2 - l') |l'\rangle \quad || \quad l(l+1) = l'(l'-1)$$

$$\Rightarrow \boxed{l' = -l}$$

Logos for NPTEL and CDEEP IIT Bombay are visible on the slide.

So, it becomes equal to J x square plus; so one step J x square plus J y squared, but plus J z on l prime. So, that is equal to J squared minus J z square, but plus J z on l prime and this is equal to 0. So, this implies that J squared which we already determine was equal to l into l plus 1 is equal to minus l prime squared plus l prime. So, replacing these operators by the Eigenvalue on l prime; that means, that l prime must be equal to minus l.

So, the only way this will be satisfied if this is true alright. So, we have transferred it to this side thank you, so, this 0 equal to this. Therefore, J square on this equal to l prime square minus l prime.

Student: (Refer Time: 24:46).

Right? Yeah. So, this means that l prime is equal to minus. So, we get l into l plus 1 is same as equal to l prime into l prime minus 1 and this quadratic will be solved only by l prime equal to minus l. So, we get the famous result that the lowest value of m z will simply be equal to minus of the highest value.

(Refer Slide Time: 25:51)

Handwritten mathematical derivation on a slide:

$$(J^2 - m^2) \geq 0$$

Thus, $J^2 = L + L'$

$$= (J^2 - J_z^2 + J_z) |L'\rangle$$

$$\Rightarrow J^2 = L(L+1) = (L'^2 + L') |L'\rangle \quad || L(L+1) = L'(L'-1)$$

$$\Rightarrow L' = -L$$

Thus we checked the steps reqd to show the spectrum of eigenvalues for m is either integer or $\frac{1}{2}$ -integer.

So, these are all the famous results and we can so now we discuss this spectrum for so thus we have proved thus we checked the steps required to show that the spectrum of Eigenvalues. So, i am using deliberately this word spectrum of Eigenvalues because that is what they are called. In all the advanced Hilbert space theory also the Eigenvalue is called Eigenvalue of spectrum. So, if you have ever seen a spectrograph the way it split out the spectral lines it is like spectrum that goes on forever.

So, these we have check the; to show that either you have half integers Eigenvalue or integers Eigenvalues for l ; I should say m no for m is either integer or half integer or half integer. Some comment I wanted to make here so correspondingly we get spin the half will not be admissible for the real algebra and integer will be used for the angular momentum algebra, but some one more comment I wanted to make oh yes and right and the point is that each one of these; is one irreducible representation.

(Refer Slide Time: 28:10)

Finally, for each fixed
" J^2 " = $l(l+1)$
we get one irrep. of the commutator
algebra of $\{J_i\}$
And since $U = \exp\{i\theta \hat{n} \cdot \vec{J}\}$ the same
irrep.s work for the group.

Integer spectra for $SO(3)$
Both integer & $\frac{1}{2}$ -integer for $SU(2)$.

CDEEP
IIT Bombay
PH 50PL / Slide

NPTEL

For each fixed J^2 equal to $l(l+1)$ we get one irreducible representation of the let us for the time being say the commutator algebra of J 's J_i , but because the group itself is obtained as exponentiation of J_i this multiplet will also work as the represent irreducible representation of the group; integer spectra for $SO(3)$ and both integer and half integer for $SU(2)$. So, that is the final summary.
