Lecture – 42
Lorentz Boosts, $SO(3,1)$ Algebra – II

(Refer Slide Time: 00:17)

Now, next we go to generators. So, here we have to look at the infinitesimal transformations. The infinitesimal transformations are so all we have to do is look at those transformation matrix.

(Refer Slide Time: 00:59)

Let $\beta = \tanh \zeta$
 $\gamma = \frac{1}{\sqrt{1-\beta^2}} = \cosh \zeta$; $\gamma\beta = \sinh \zeta$

$-1 < \beta < 1$
 $-\infty < \zeta < \infty$

$\therefore \begin{aligned} c\Delta t' &= \cosh \zeta (c\Delta t) + \sinh \zeta \Delta x \\ \Delta x' &= \sinh \zeta (c\Delta t) + \cosh \zeta \Delta x \end{aligned}$

compare

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} \cosh \zeta & -\sinh \zeta \\ \sinh \zeta & \cosh \zeta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \quad ; \quad \begin{pmatrix} c\Delta t' \\ \Delta x' \end{pmatrix} = \begin{pmatrix} \cosh \zeta & \sinh \zeta \\ \sinh \zeta & \cosh \zeta \end{pmatrix} \begin{pmatrix} c\Delta t \\ \Delta x \end{pmatrix}$$

PH 5301 / Slide 7

It is in the other language yeah this language is cosh, sinh, sinh, cosh they have just the same kind of expansion say sin and cosine except for the fluctuate, or the most important difference between the rotations. And these is aside from the fact that there are hyperbolic trigonometric functions, there is a minus sign here, and the plus sign here.

This sign these signs are always opposite for real rotations depending on the convention use the minus sign may be here or there, but they are oppositely signed, whereas, in boost these will always be the same signed. So, if it was boost in the opposite direction then both the sine hyperbolic's will change sign and you will get both minus signs.

(Refer Slide Time: 01:52)

$\therefore \Delta t' = \cosh \beta (\Delta t) + \sinh \beta \Delta x$
 $\Delta x' = \sinh \beta (\Delta t) + \cosh \beta \Delta x$

compare
 $\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} \cosh \beta & -\sinh \beta \\ \sinh \beta & \cosh \beta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \quad ; \quad \begin{pmatrix} \Delta t' \\ \Delta x' \end{pmatrix} = \begin{pmatrix} \cosh \beta & \sinh \beta \\ \sinh \beta & \cosh \beta \end{pmatrix} \begin{pmatrix} \Delta t \\ \Delta x \end{pmatrix}$

Generators: Look at infinitesimal transfs
 $\begin{pmatrix} \cosh \beta & \sinh \beta \\ \sinh \beta & \cosh \beta \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \beta \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} + O(\beta^2)$

4x4 notation, $K_1 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$ $K_2 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$ $K_3 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}$
 $\equiv K_x$

So, in the present case cosh psi, sinh psi if you expand out the cosh it is 1 to first order. And then there will be psi times 0 1 1 0. The sinh series is just the odd powers with divided by the number factorial with no sign changes their both essentially becoming exponential for large.

So, there are no sign fluctuating signs and this is all we have and plus order psi squared which will come for the expansion of cosh, but we look at the linear term then this is all we have. So, in 4 d notation we have K_1 which is same as K_x equal to so we call it K_x 0 1 1 0 0 0 0 and the 3 by 3 part which is rotations will be a big 0. But as I said as per Steven Weinberg's notation I will fill it with 0's then K_2 which is same as K_y would be equal to 0 0 1 and 0 and 0, 1 and 0.

So, the one just migrates along the top and the bottom and this 3 by 3 sub matrix of rotations remains null and does not require much imagination to, so you can fill it out 0 0 0 1 and 0 1 and all other 0's. Now, just as for the rotation matrices we would like to know the algebra of these.

So, we have to see what these things do under mutual commutation algebra of boost generators, K_i . Now, here is where I run into lot of grief with signs and I hope that you will bear with me. So, I have some notes actually I will put these up, but I found that the notes has sign problem.

(Refer Slide Time: 05:11)

Algebra of boost generators K_i :

$$\begin{aligned}
 & \overset{K_x}{\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}} \overset{K_y}{\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}} - \overset{K_y}{\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}} \overset{K_x}{\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}} \\
 &= \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} - \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} = -L_z = iJ_z
 \end{aligned}$$

Thus expect $[K_i, K_j] = i \epsilon_{ijk} J_k$

exts K_x J_z

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} - \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

NPTEL

So, you should believe the results I tell you and work out the matrix multiplication yourself, but let us since there is time and since we never have any tutorial hour let us try to do $K_x K_y$ and see what we get? $K_x K_y$ and commutator, so $0 \ 1 \ 0 \ 0$, $1 \ 0 \ 0$ and if you do want to save time put 0 here and then $0 \ 1 \ 0 \ 0 \ 1 \ 0$ big 0 here.

Now, yeah I am trying to put K_y first and times K_x . So, what do we get? So, the only non-zero term here is the one that comes from second row and third column, so second row and minus third row and second column.

This is equal to our old friend L_z all right yeah L_z had so this is minus of L_z , this is L_z because it is in the one two location. So, this is giving $x \ y$ rotation basically with 1 here, and a minus 1 here. And our convention the way I remember we introduced the active rotations was that this is equal to minus of L_z and therefore, is equal to i times J_z we had set J_z equal to i times L_z ; J_z equal to i times L_z .

So, L_z equal to minus i times J_z , so minus L is equal to i times J_z . So, we expect that $K_i K_j$ to produce i times j epsilon $i \ j \ k \ J_k$ if I take K_x and K_y right this is K_x and this is K_y and it produce J_z . So, we expect that the algebra is $K_i K_j$ to produce i times J epsilon $i \ j \ k$ this. The next thing to check is what happens between j and k ? And this is where I had some problem with.

So, you will see where the sin crops up in a most important why most of this that we are writing it does not really matter, but anyway let me in next try to do K_x and J_z . So, can you do K_x and J_z in your book and better fill out everything whereas, J_z is equal to i times L_z and L_z has 1 here, so that is i and minus i ok.

(Refer Slide Time: 11:17)

$$= \begin{pmatrix} 0 & 0 & i & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} - \begin{pmatrix} -i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} = iK_y$$

Thus expect $[K_x, J_z] = iK_y$
 So expect $[J_z, K_x] = -iK_y$
 $\rightarrow [J_i, K_j] = -i\epsilon_{ijk} K_k$
 Summary: $[J_i, J_j] = i\epsilon_{ijk} J_k$

Logos: CDEEP IIT Bombay, NPTEL

So, next consider this all the other things are going to be 0, and minus third row into second column which is going to be equal to minus i sorry so minus i . So, what do we get? We get i times K_x is not it K_y so, thus we expect that K_i .

So, let us first write $K_x J_z$ was equal to i times K_y . So, what do we expect? K_i , but this is in reverse order so, we should such that x would be more correct would be minus. So, better write it as J_i very sorry. So, this is same as $J_z K_x$ equal to minus $i K_y$, or $J_i K_j$ equal to minus $i \epsilon_{ijk} K_k$. So, now, we have this algebra all this looks pretty boring, but now something interesting happens.

So, summary by the way this is what out in Jackson Jacksons Electrodynamics book chapter 13 has all this written out in great detail. He does not use complex notation, but I did try to check the sign, but there are all these binary choices do you use active rotations or passive rotations do use active boosts or passive boosts you write j first or k first.

So, the signs have to be worked out, but it is all there in Jackson's book electrodynamics book it is there chapter 13 I think especially relativity. So, we are not doing something all

the terribly exotic so far. But now let us see what is the summary? Firstly, we had the good old $J_i J_j$ equal to $i \epsilon_{ijk} J_k$.

(Refer Slide Time: 15:13)

Thus expect $[K_x, J_z]$

Next, K_x J_z

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & i & 0 \\ 0 & -i & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} - \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & i & 0 \\ 0 & -i & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$[J_z, K_x] = -i K_y$ "Jackson Edyn. Chap 12"

$[J_i, K_j] = -i \epsilon_{ijk} K_k$

Summary:
Lorentz Group algebra

$$\begin{aligned} [J_i, J_j] &= i \epsilon_{ijk} J_k \\ [K_i, K_j] &= -i \epsilon_{ijk} J_k \\ [J_i, K_j] &= -i \epsilon_{ijk} K_k \end{aligned}$$

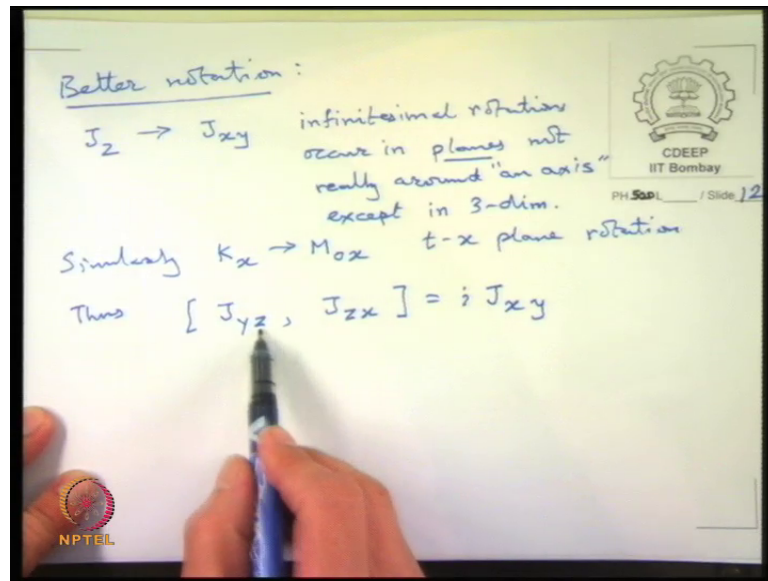

Then we calculated $K_i K_j$ equal to $i \epsilon_{ijk} J_k$. And finally, we had $J_i K_j$ which is equal to minus $i \epsilon_{ijk} K_k$ this is the total $SO(3,1)$ algebra, or the Lorentz group algebra.

What is interesting to note is that if you have two boosts if you do if you come you two successive boosts you actually get a pure rotation. So, in atomic physics this was discovered because some factor half was not coming out correctly it is called Larmor precession if I am not mistaken.

So, Larmor physically worked out the electron orbiting the atom and then it is here and then it is there. So, there are two successive boosts those successive boosts amount to a rotation of the electron. So, and we will have where I will tell you a little more about it quickly soon.

So, two sets two boosts commute to give a rotation, but then a rotation and a boost mix things produces a boost. Now let us try to understand physically what this why it is like this? So this is the boxable result and I hope that sings in it are all correct.

(Refer Slide Time: 17:30)

So, let us understand and write an easier way of remembering this. So, the better notation actually is to remember that the z rotation is actually x y plane rotation. The when we say that I rotate around z axis, this is a convenience of 3 dimensions, because actually the rotation is happening in x y plane and to say that it is around z axis, there is a unique third axis in only in 3 dimensions in many dimensions are would be many many axis that are orthogonal to x y.

So, they are calling it as z rotation is actually just a luxury of 3 D really speaking J_z is actually J_{xy} ok. So, the rotation infinitesimally rotations are in planes occur in planes not really around an axis except in 3 D.

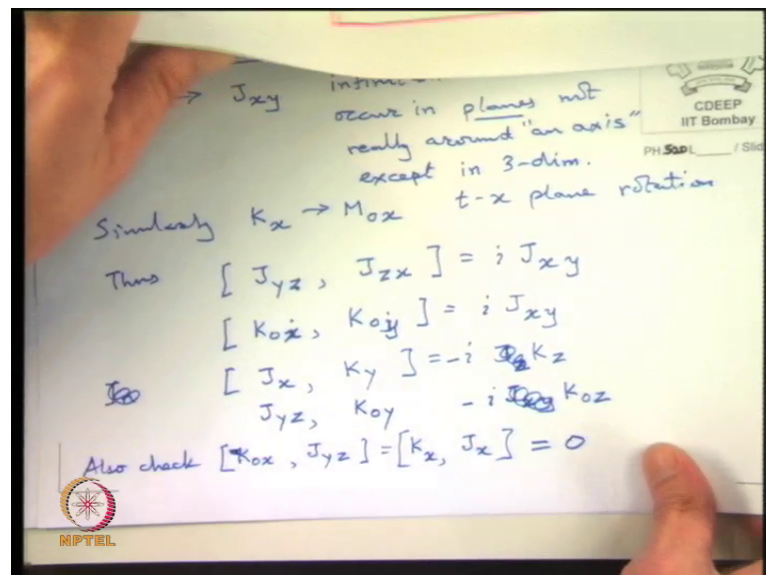

In fact, this is the reason I can now tell you if you have suffered with this notion all along. Why is it that I have to take when I take cross product I have to erect it perpendicular to the plane in which I take the cross product ok, and I have to use right hand screw rule.

What happens if I use left hand screw rule? Well they say it is matter of convention well if it is convention it can be very physical right. So, if there is actually no perpendicular vector sticking out of the planes it is actually within the plane and it is it is basic the rotation is actually a second rank tensor, and not a vector. So, the correct way may so maybe we will come to that at some other point even we come to representations, for the

time being note that actually it is not the axis of rotation. So, it is a two index object not really one index object.

So, similarly the K_x is basically let us call it M_{0x} , there is time and space ok, so the K_i are basically $t-x$ plane rotations. If you now think like this then we know J remember what we use to write $x-y-z$. So, x is actually $y-z$ and y is $z-x$ is equal to i times J . So, $x-y$ would have given $J-z$, but z is equal to $x-y$ this is what the commutation algebra is. And what does this say? It says that if there is a $y-z$ rotations let us similarly write down say this $K_i K_j$.

(Refer Slide Time: 21:30)

So the $K_{0i} K_{0j}$ becomes equal to i times J . So, let us be specific so make it 0_x , and 0_y then from this algebra we know that this is J_z , but z is equal to $x-y$. Now, what do we see common between these what is happening is that if I have a $y-z$ rotation followed by $z-x$ rotation not really followed by commutation then does that drop out and I am left with an $x-y$ plane rotation $x-y-z$ becomes $x-z$ directly.

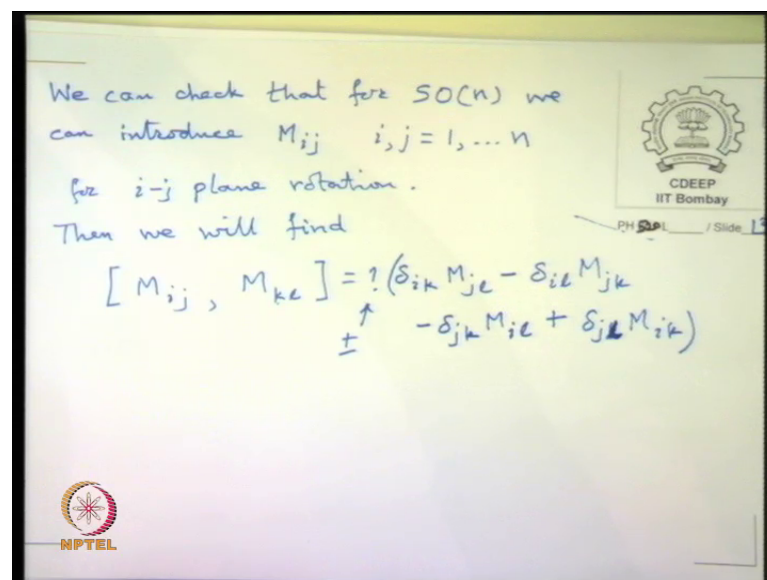

If I have 0_x , and 0_y then I the 0 drops out and I basically get an $x-y$ rotation. If I have larger number of dimensions, if I rotate 1, 2 plane and 7, 9 plane and later I rotate 7, 9 first and 1, 2 they are going to be independent, they will all commute. So, those rotations that share one axis are equivalent to the rotation which is the two un where there shared axis drops out. So, if it is z and z then there is no z here, 0 and 0 there is no 0 here.

So, I said from sin conventions that is what is happening ok. And in general we will have. So, we can also quickly check the third thing where if I take J_x and K_y I should get i times. So, which is sorry so which is same as J_x is equal to $y z$ and K_y is $k \theta y$.

What do I get? I get from this $J_x x y$ is equal to minus $i J_z$ becomes equal to z is equal to minus $x y$; x is equal to yeah sorry this is k sorry thank you that is why I was going wrong. So, it becomes $K \theta z$, that again we see the same rule if it is $y z$ and θy then y is going to drop out and I will get a θz rotation. So, this is basically how the algebra operates and therefore if you go to larger dimensions then planes that are independent that do not share any access they will just commute.

So here too you can think of θx , and $y z$. So, also check this should be equal to 0, so $y z$ is equal to J_x , but according to this algebra if the two indices are because there is a epsilon tensor here if these two are equal this is 0, so this is indeed 0. So, if you have completely independent planes θx plane and $y z$ plane then the commute that is the moral of this whole exercise and that is it is basic geometry it captures the geometry of rotations.

(Refer Slide Time: 25:49)

We can check that for SO_n we can introduce well first let us just say M_{ij} with i, j running over 1 to n for i, j plane real rotation. Then we will find. What do you expect? $M_{ij}; M_{kl}$ to be equal to what?. So, I am guessing if i equals k then I will drop out and $J_k j l$ will remain.

So, $\delta_{ij} \delta_{kl} M_{jl}$ then there will be a so next if i equals l then I should put δ_{il} and i should be left with M_{jk} except that because I am matching first sign with a second sign there will be a relative minus sign.

Similarly a relative minus sign and $\delta_{jk} M_{il}$ and finally, j equal to k M_{ik} and the overall sign I do not know it is plus or minus 1 that one has to check by checking one of them correctly in detail. But this is what we expected to be if the top infinitesimal rotations share any one axis then we get an only if the share one x axis then we get a non-zero answer. And if neither i equals k nor, if i does not equal k or l and j does not equal k or l then we will get 0 that is this.

So, S_1 algebra will be like this we worked it out you know no need to be afraid of higher number of dimensions yes ok. So, that is see first one I put as δ_{ik} and j l in the end I should put δ_{jl} and i k right. So, aside from an overall sign which you can fix so when string theories tell you we have to living 10 dimensions you have to sum prepared I can rotate internet. So, this is algebra of SO_n .

(Refer Slide Time: 29:42)

Representations for the Lorentz Group

Introduce $A_i = \frac{1}{2} (J_i + iK_i)$
 $B_i = \frac{1}{2} (J_i - iK_i)$

$$[A_i, A_j] = \frac{1}{4} [J_i + iK_i, J_j + iK_j]$$

$$= \frac{1}{4} \{ [J_i, J_j] + i[K_i, J_j] + i[J_i, K_j] - [K_i, K_j] \}$$

$$= \frac{1}{4} \{ i\epsilon_{ijk} J_k + i(i\epsilon_{ijk} K_k) + i(i\epsilon_{ijk} K_k) + i\epsilon_{ijk} J_k \}$$
~~$$= \frac{1}{2} i \epsilon_{ijk} (J_k + iK_k)$$~~

$$= \frac{1}{2} i \epsilon_{ijk} (J_k + iK_k) = i\epsilon_{ijk} A_k$$

Now, we come back to the algebra of $SU(2)$ and there are some interesting things here. So, representations of the Lorentz group for now when we had the 3D rotations, we at this clever J plus J minus construction. But now we have 6 generators corresponding to the 6 parameters. So, by the way I hope you know how to count these are the they have to be orthogonal. So, only the upper triangle matters the lower triangle is minus of

those that are above and the upper triangle in 4 by 4 matrices is 6, so there are 6 parameters.

And how do we generate the representations? So, here there was this clever trick by Herman Weyl it says the following; so by the way Dirac was considered a wizard by most people of his generation and later once we have radius papers and Dirac was famous for not answering anything in more than one word at a time monosyllabic yes no maybe or keep quiet say nothing.

So, there if you Google interview of Paul Dirac, that I think it was university of Wisconsin or Minnesota one of these northern university. So, interview of Paul Dirac you will find this one webpage of an interview taken by a response in journalist and it is an American journalist. So, he goes and says Professor Dirac can I interview you and all this.

So, and Dirac is sitting there yes no no; so he is asking you are you the greatest genius has no, so and it goes on. So, eventually Dirac gets bored. So, I just kind of gets up and starts living and then this man says wait wait, but tell me whom do you consider clever who are you scared of or something like this, who would you think is yours superior and Dirac stops and says while and leaves the room.

So, that Herman Weyl suggested that what we should do is to define A_i equal to and I hope I pull this off correctly I feel like Harry Potter movie and try to do some magic and should work.

There is an i introduced, so and b_i are of course, with the opposite sign minus i K_i . So, there are two independent linear combinations introduced and now let us see what we get with their commutation. So, if I take A_i, A_j so here what we did was there is i times $K_i J_j$, but I have here a J_k commutator.

So, to reverse order of J and K I get a minus sign on the commutator which I put here, but now the order of J_i has got reversed. So, if I change order of J_i and the epsilon I get a minus sign. So, there is so firstly, became plus i , but then a minus because the epsilon sign change, so I get a minus i this is straight forward.

So, I get both plus signs which looks very good except that $J_i J_j - J_j J_i$ should also have given i times, so these two should have added. So, I claim that this is equal to one half times i times epsilon $i j k$ times J_k plus. So, if I pull out and I then I will get a everything is here is wrong I get a minus i going to change the sign here and put this sign here. So, these signs have to be reversed ok.

How would we did the whole matrix multiplication? But I do not know how I got it wrong, but if this is minus, this is plus, then this will become plus, this will become plus, and I will have a minus sign and the K_k commutator as a minus sign. So, that will cancel this and so I get totally one half times i times epsilon $i j k$ times J_k plus i because this is this becomes now a minus epsilon $i j k$ K_k , so it becomes this. So, equal to i times epsilon $i j k$ A_k .

So, we need to fix these signs $K_i K_j$ equal to minus i epsilon $i j k$ J_k let me just try to think if I were not to do this anyway right now there is there are binary choices so that I told you. And if you flip some signs and some signs will change I do know that this is all this also in some convention this is the algebra and so let me just write down the book name.

(Refer Slide Time: 38:20)

Summary:
Lorentz Group algebra

$$\begin{aligned} [J_i, J_j] &= i \epsilon_{ijk} J_k \\ [K_i, K_j] &= -i \epsilon_{ijk} J_k \\ [J_i, K_j] &= i \epsilon_{ijk} K_k \end{aligned}$$

Ramond convention
*Field Th. a Primer

$$\begin{aligned} &= \frac{1}{4} \{ [J_i, J_j] + i [K_i, K_j] + i [J_i, K_j] - i [K_i, J_j] \} \\ &= \frac{1}{4} \{ i \epsilon_{ijk} J_k + i (-i \epsilon_{ijk} J_k) + i (i \epsilon_{ijk} K_k) + i \epsilon_{ijk} J_k \} \\ &= \frac{1}{2} i \epsilon_{ijk} (J_k + K_k) = i \epsilon_{ijk} A_k \end{aligned}$$

NPTEL

This is it field theory a primer, modern primer. So, if you use this conventions and then introduce these A 's. Then the A_i satisfy exactly as if it is $SU(2)$ algebra. More importantly A and B mutually commute.

(Refer Slide Time: 38:59)

$$= \frac{1}{4} \{ i \epsilon_{ijk} J_k + i (i \epsilon_{ijk} K_k) + i (i \epsilon_{ijk} K_k) + i \epsilon_{ijk} J_k \}$$

$$= \frac{1}{2} i \epsilon_{ijk} (J_k + i K_k) = i \epsilon_{ijk} A_k$$

$$[A_i, B_j] = 0$$

$$[B_i, B_j] = i \epsilon_{ijk} B_k$$

i.e. $\{A_i\}$ & $\{B_i\}$ $SU(2)$ algebras
which are indep. of each other

Thus $SO(3,1) \simeq SU(2)_A \otimes SU(2)_B$

So, this we can check by just running through this algebra because if you want to calculate $A B$ commutator all you have to do is replace this by minus sign, but you can see that changing that sign does all the mischief. Because this first term will remain the same this term will change sign because of this and this, but K_j will not change sign and K_k will change sign.

So, the relative signs of the things that was supposed to add actually become opposite and A and B then commute and finally, we can work out $B_i B_j$ this turns out to be not surprisingly $i \epsilon_{ijk} B_k$ because once you here change both of these signs then everything will remain as it is except for the overall sign here and you will get a $j k$ minus $i K k$.

So, the summary is that A and B $SU(2)$ algebras which are mutually commuting independent of each other right the A is satisfy $A_i A_j$ equal to $i \epsilon_{ijk} A_k$, B satisfy the same and the $A B$ mutually commute. So, we saying group theory a $SO(3,1)$ is this is the special sign equivalence $SU(2)_A \otimes SU(2)_B$ it boils down to some $SU(2)$'s. There is there are not genuine $SU(2)$ there pseudo $SU(2)$'s because of the introduction of the I in this convention, but then nor is this is a full orthogonal group.

So, system $SO(3,1)$, but this trick allows us to reduce at least the representations of Lorentz group to 2 $SU(2)$ groups, it is just like two different spins. So, the A can take any value minus L to plus L and B can $L A^2$ plus minus $L A^2$ plus $L A L$ as independent

quantum number going from minus $L B$ to plus $L B$. So, we will see more about it next time.
