Lecture No. # 10
Electrostatic Waves in Plasmas

Well friends, so far we have discussed the propagation of electromagnetic waves in plasmas, well last time we were discussing a very special kind of wave phenomena, the W K B solution to wave propagation inhomogeneous plasmas, and we considered the propagation of wave in the direction of density gradient.

When we were considering the propagation of waves at oblique angle to density gradient, we came across a situation where the wave turns around, and there is a possibility of generation of plasma waves. So before I take over to the discussion of wave propagation at oblique angles to density gradient, I think it is necessary that we understand the character of electrostatic waves.

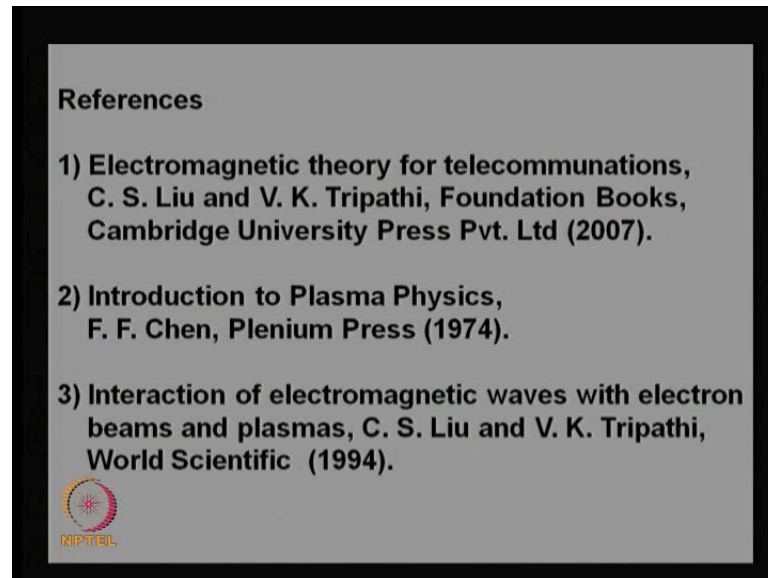

(Refer Slide Time: 01:23)

So, today I am going to start rather a new subject that is the propagation of electrostatic waves in plasmas, in this we will discuss how to express an electric field in terms of a potential.

Then, how to linearize the fluid equations? The equation of motion, and equation of continuity; and deduce expressions for electron and ion susceptibilities. And then to discuss specifications of Langmuir waves and ion acoustic waves, which exist in unmagnetized plasmas as well as in magnetized plasmas also. So, today our presentation will focus on waves in unmagnetized plasmas.

(Refer Slide Time: 02:05)

Well, I would like to refer to three books; one is electromagnetic theory for telecommunications written by professor C S Liu and myself published by foundation books Cambridge university press. Second is introduction to plasma physics by F F Chen published by Plenum press and third one is interaction of electromagnetic wave with electron beams in plasmas by professor C S Liu and myself published by world scientific.

(Refer Slide Time: 02:54)

$$\begin{aligned} \epsilon_{\text{eff}} = 0 & \quad \text{ES Wave} \\ \vec{k} \cdot \vec{E} = 0 & \quad \text{EM Wave} \\ \nabla \times \vec{H} &= -i \omega \epsilon_{\text{eff}} \vec{E} \epsilon_0 \\ \nabla \cdot \vec{H} &= 0 \\ \vec{H} &= 0 \end{aligned}$$

Well, as I mentioned that in order to satisfy the Maxwell's equations for plane wave solutions it was necessary that either you satisfy epsilon effective equal to 0 condition or k should be perpendicular to E or $k \cdot E = 0$, the second is the case when electric field is perpendicular to k vector of the wave is called EM wave electromagnetic wave and we have discussed this case. Second possibility is that plane wave solution can satisfy Maxwell's equations, when epsilon effective is 0 and in this case the waves are known as electrostatic waves.

For these waves please understand one thing that according to fourth Maxwell equation curl of H is equal to minus $i \omega \epsilon_{\text{eff}} E$ into ϵ_0 of course, So, if right hand side is 0 then curl of H is also 0 and according to second Maxwell's equation curl of B is also 0 a dot of divergence of H is also 0 .

When curl of a vector is 0 and divergence also 0 then the vector must vanish, well we had also see this explicitly last time that H is 0 for these waves. So these are purely electric waves and we call them as electrostatic waves.

(Refer Slide Time: 04:40)

The image shows a chalkboard with the following handwritten equations:

$$\nabla \times \vec{E} = - \frac{\partial \vec{B}}{\partial t}$$
$$= 0$$
$$\vec{E} = - \nabla \phi(\vec{r}, t)$$
$$\nabla \cdot \vec{D} = \rho, \quad \vec{D} = \epsilon_0 \frac{\text{eff}}{E}$$
$$\epsilon_0 \nabla^2 \phi = -\rho$$

In the bottom left corner of the chalkboard, there is a small circular logo with the text "NPTEL" below it.

Now, before I move further I would like to examine the third Maxwell equation which is curl of E is equal to minus delta B by delta t.

If, there is no magnetic field associated with the wave then delta B by delta t is 0 and curl of E is 0. any vector whose curl is 0 is expressible in terms of a gradient of a scalar quantity I express this E then as minus gradient of a function phi which may depend on position and time in general, so an electrostatic wave electric field is expressible in terms of a potential phi which in general depends on position and time.

I would like to understand in terms of phi, what is the wave equation governing phi? And in terms of phi what is the response of electrons and ions to this potential. first of all a word about the Maxwell's equations there are four Maxwell's equations, second Maxwell equation I had already written divergence of H is 0, so when H is 0 this equation is not meaningful.

Third equation is this equation, so if H is 0 then curl of E is 0 so when I express E in terms of phi this equation is automatically satisfied. how about the first Maxwell equation when you use this E in the first Maxwell equation which is divergence of D is equal to rho and for plasmas we write D as epsilon 0 into effective **sorry** this is for this is not true I made a mistake let me delete this for plasmas D is equal to epsilon 0 into E Simple product of free space permittivity and electric field but polarization we ignore.

So, if I write E as $-\nabla\phi$ this equation becomes $\epsilon_0 \nabla^2 \phi = -\rho$, and ρ is expressible in terms of electron and ion densities thus this is the equation that governs, the variation of potential in terms of electron and ion densities and if we can express electron and ion densities in terms of ϕ then this becomes the wave equation. So as far as the electrostatic waves are concerned this is equivalent of a wave equation.

(Refer Slide Time: 08:03)

The whiteboard shows the following equations:

$$n = n_0 + n_1$$

$$n_i = n_0 + n_{i1}$$

$$\nabla^2 \phi = -\frac{1}{\epsilon_0} (n_{i1}e - n_1e)$$

$$\nabla^2 \phi = \frac{e}{\epsilon_0} (n_1 - n_{i1})$$

Wave Eq. for ES Wave

NPTEL

Let me write this, in terms of electron and ion densities initially the electron density in the plasma is n_0 and ion density also is n_0 . however when a wave travels these densities are modified suppose this becomes n_1 and this becomes n_{i1} in that case the Poisson equation or first Maxwell equation becomes $\nabla^2 \phi = -\frac{1}{\epsilon_0} \rho$ where ρ is the net charge density. If, I multiply by the electron charge which is $-e$ and the ion density by ion charge which is $+e$ then it becomes $\nabla^2 \phi = \frac{e}{\epsilon_0} (n_1 - n_{i1})$.

Because, the n_0 and n_0 terms here will cancel each other, so take e out you can write this as $\nabla^2 \phi = \frac{e}{\epsilon_0} (n_1 - n_{i1})$ this is the wave equation for electrostatic waves in a plasma, if we could write n_1 and n_{i1} in terms of ϕ well this Poisson equation we will use little later.

Let us go over to the fluid equations which governed the response of electron to ϕ but, a word about the character of these waves probably will be in order at this stage.

(Refer Slide Time: 10:11)

Eq. of motion

$$m \left(\frac{\partial \vec{v}}{\partial t} + \vec{v} \cdot \nabla \vec{v} \right) = -e\vec{E} - \frac{1}{n} \nabla(nT_e)$$
$$\frac{\partial n}{\partial t} + \nabla \cdot (n\vec{v}) = 0$$

We are talking of waves going in some direction, which I call as the direction of propagation k . Because, the electric field of these waves in the direction of k at any instant if you look then the field of these waves will appear like somewhere in this direction somewhere in this direction somewhere in this direction at a given instant of time.

And then these arrows will move in the forward direction with time with the phase velocity of the wave, what is the consequence of these fields having opposite directions in different positions that for instance the electrons they will experience a force opposite to the electric field they will move in this direction whereas, the electrons which are here they will move in the in this direction.

So, in this region the electrons are moving away from each other and there will be a decrease in electron density. In this region there will be a buildup of electron density, so what you would expect is that in course of wave propagation charges accumulate in these regions they are accumulated there they are accumulating there they are accumulating there and they are there is a rarefaction there. So, with the propagation of electrostatic wave you are going to expect electron density oscillations and electron density oscillations are connected to velocity through the Poisson through the equation of continuity and hence let us write down the equation of motion.

Equation of momentum balance or equation of motion that is normally called is written as $m \frac{dv}{dt} + v \cdot \nabla v = -eE$, which I write as $-eE$, I will ignore the presence of DC magnetic field and there is no magnetic field (()) the wave so I will not write the magnetic force. But, then there is a collisional force for the sake of simplicity for the moment I may ignore the collisions also then there is a term called pressure gradient force which is $\frac{1}{n} \nabla n$.

This is the equation of motion for electrons of charge $-e$, Mass m , density n and temperature T , I can write T_e electron temperature T_e .

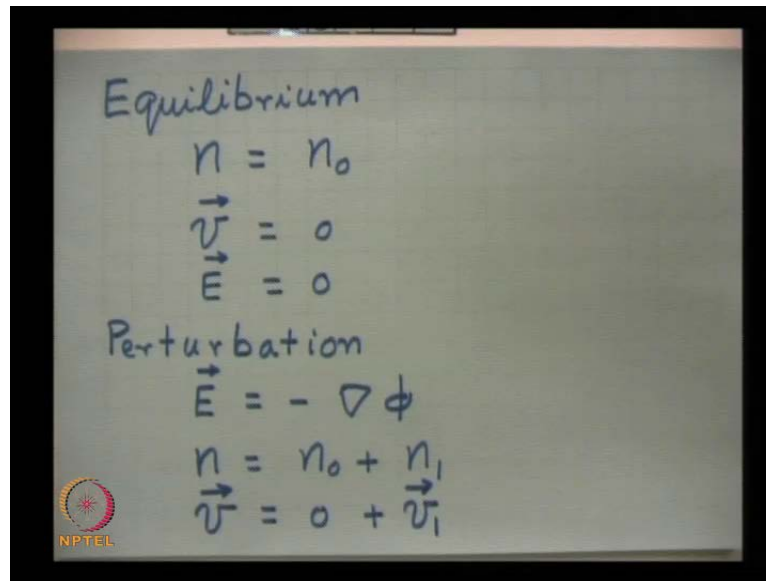

So, equation of momentum balance involves density and the equations density is the equation of continuity $\frac{dn}{dt} + \nabla \cdot (n v) = 0$, these two equations are non-linear, why? Because, in these equations I can treat E as the source and v as the response and n also as the response. So whenever there is an electric field produced by a wave in the medium the electrons will respond to the field and they are called the response the velocity is the effect E is the cause.

Similarly, I can treat density also as variation in density also as the effect caused by this electric field, if electric field of the wave is small then response will also be v and product of two perturbed quantities or weak quantities I can ignore this process is called linearization. So, in order to solve a non-linear set of equations the first step is to linearize them linearization means neglect the terms which are of first order, even prior to that let us find out what are the equilibrium values of various quantities in these equations.

These equations govern the density and drift velocity average velocity of electrons. In equilibrium when there was no electrostatic wave in the system obviously I was not expecting a drift velocity, so in equilibrium $v = 0$ and the density of electrons was n_0 and ion density was also n_0 because the plasma was electrically neutral and how about temperature. If the electric field is of very small amplitude then it does not cause significant heating, so electron temperature also remains constant.

So, first whenever you have to solve a set of non-linear coupled differential equations or partial differential equations, you must always start with the equilibrium it is a general technique employed for electromagnetic waves as well as electrostatic waves.

(Refer Slide Time: 15:30)

Equilibrium

$$n = n_0$$
$$\vec{v} = 0$$
$$E = 0$$

Perturbation

$$\vec{E} = -\nabla\phi$$
$$n = n_0 + n_1$$
$$\vec{v} = 0 + \vec{v}_1$$

NPTEL

So, first of all let me write down the equilibrium an equilibrium my density of electrons is equal to n_0 . And drift velocity of electrons is 0 and temperature just a constant, so I do not bother about it then I perturbed the system there is no electric field.

Now, I perturb this equilibrium so let me write the perturbation, I am writing my electric field E is equal minus grade ϕ and I am treating these E to be a perturbed quantity and ϕ , well I will explicitly write ϕ in terms of position and time little later but, then when the electric field of the wave is there in the system density I would expect to become n_0 plus some change called n_1 . And how about the drift velocity? The drift velocity was 0 in the beginning there is a value given it acquires because of the wave called v_1 but, I will treat this ϕ n_1 and v_1 all small quantities and in the process of linearization of those equations of motion and continuity I will ignore the product of these quantities.

(Refer Slide Time: 17:29)

Linearized Eq. of motion

$$m \left(\frac{\partial \vec{v}_1}{\partial t} + \vec{v}_1 \cdot \nabla \vec{v}_1 \right) = e \nabla \phi - \frac{T_e}{n_0 + n_1} \nabla n_1$$

≈ 0

$$\frac{\partial \vec{v}_1}{\partial t} = \frac{e}{m} \nabla \phi - \frac{T_e/m}{n_0} \nabla n_1$$

≈ 0

NPTEL

So, let me first write down the linearized equations of motion and continuity, so linearized equation of motion this equation is $m \frac{\partial \vec{v}_1}{\partial t} + \vec{v}_1 \cdot \nabla \vec{v}_1 = e \nabla \phi - \frac{T_e}{n_0 + n_1} \nabla n_1$ just substituting for v equal to v_1 in the equation of motion right hand side is $e \nabla \phi$ is the electric field electric force then there is a pressure term which is I take constant temperature so T comes out of this upon $n_0 + n_1$ gradient of n_1 , because gradient of n_0 is 0 this is the acquisition of motion.

Now by linearization, what do I mean? I am going to ignore the product of perturbed quantities v_1 is a perturbed velocity so the product of two perturbed quantities will be ignored so I take this term to be 0. Now, as far as this term is concerned n_1 is the perturbation and n_0 is the original value of density, so n_1 is very small and n_0 is large. If, I carry out a binomial expansion of this factor n_1 term will go up and product of n_1 with n_1 will be ignored.

So rather than going through that step I just ignore this here so this term is nearly 0, because this is already perturbed quantities there. So with their neglect of this term and this term this equation becomes a linear equation or linearized equation, which I can write down as $\frac{\partial \vec{v}_1}{\partial t} = \frac{e}{m} \nabla \phi - \frac{T_e}{m n_0} \nabla n_1$; this is the equation of motion after linearization.

(Refer Slide Time: 20:16)

$$\frac{\partial n_1}{\partial t} + \nabla \cdot [(n_0 + n_1) \vec{v}_1] = 0$$
$$\frac{\partial n_1}{\partial t} + \nabla \cdot (n_0 \vec{v}_1) = 0$$
$$\phi = A e^{-i(\omega t - \vec{k} \cdot \vec{r})}$$
$$n_1, \vec{v}_1 \sim e^{-i(\omega t - \vec{k} \cdot \vec{r})}$$
$$\frac{\partial}{\partial t} = -i\omega, \nabla = i\vec{k}$$

Similarly, the equation of continuity the equation of continuity is $\frac{\partial n_1}{\partial t}$ by $\frac{\partial n_1}{\partial t}$, because $n_0 \frac{\partial n_0}{\partial t}$ is 0 plus divergence of n_0 plus n_1 into v_1 , the velocity n v is equal to 0 but, this n_1 is a perturbed quantity this v_1 is a perturbed, so I will ignore the product and hence this equation becomes $\frac{\partial n_1}{\partial t}$ plus divergence of $n_0 v_1$ is equal to 0, this is the linearized equation of continuity.

In order to solve these equations I presume a solution to the Poisson equation or the potential as A exponential minus i ωt minus k dot r . a wave travelling in the k direction with frequency ω suppose it has a potential of this form, potential is a scalar quantity so a is also a scalar quantity.

Now, ϕ is the source and n_1 and v_1 are the responses. So, I expect n_1 and v_1 also to vary with time and position as exponential minus i ωt minus k dot r and this helps us a great deal, because wherever $\frac{\partial}{\partial t}$ occurs I can replace by minus i ω .

So, then after linearization replace $\frac{\partial}{\partial t}$ operating over perturbed quantity as minus i ω and ∇ operator by $i k$ this is time operator and this is space operator. So then these equations the equation of motion continuity with this substitution of these operators in terms of the algebraic quantities they become algebraic equations and let me write them.

(Refer Slide Time: 23:04)

$$\begin{aligned}
 -i\omega \vec{v}_1 &= \frac{e}{m} i\vec{k}\phi - \frac{v_{th}^2}{n_0} i\vec{k}n_1 \\
 -i\omega n_1 + i\vec{k} \cdot \vec{v}_1 n_0 &= 0 \\
 n_1 &= n_0 \frac{\vec{k} \cdot \vec{v}_1}{\omega} \\
 \vec{v}_1 &= -\frac{e\vec{k}\phi}{m\omega} + \frac{\vec{k} v_{th}^2}{n_0 \omega} n_1
 \end{aligned}$$

Quickly you will see, that the equation of motion becomes δv by δt is minus $i\omega$ into v_1 is equal to $\frac{e}{m} \text{grad } \phi$ minus there is a pressure term which is $\frac{T}{m}$ which I call as v_{th}^2 thermal velocity square upon n_0 gradient of n_1 grad I write as $i\vec{k}$ into density perturbation and the equation of continuity becomes $-i\omega$ into n_1 plus divergence of $n_0 v_1$ divergence del operator is $i\vec{k} \cdot v_1$ into n_0 is equal to 0.

This equation is straight away gives n_1 is equal to $n_0 \vec{k} \cdot v_1$ upon ω and this equation gives me v_1 is equal to two terms; one is minus $\frac{e\vec{k}}{m\omega}$ into ϕ , the other 1 is a plus term $\frac{\vec{k} v_{th}^2}{n_0 \omega}$ thermal velocity of electrons is square upon n_0 into ω into n_1 .

So, from the above equation if I write down the value of n_1 in terms of v_1 , I can or rather from the lower equation I use the value of v_1 , I can write down n_1 in terms of ϕ , because in order to solve the Poisson equation or Maxwell's equation I need the density perturbation, so n_1 is that is what I require and I will write down using these two equations n_1 in terms of ϕ and that turns out to be I just simplify these two equations and write the solution.

(Refer Slide Time: 25:45)

$$n_1 = \frac{-n_0 e k^2 \phi}{m(\omega^2 - k^2 v_{th}^2)}$$
$$v_{th} = \sqrt{T_e / m}$$

For $\omega \ll k v_{th}$ (Sound Wave)

$$n_1 = \frac{n_0 e \phi}{T_e} \quad \text{Adiabatic Response}$$

You obtain n_1 is equal to minus $e k^2 \phi$ there is n_0 also here, n_0 into $E k^2 \phi$ upon $m \omega^2 - k^2 v_{th}^2$ thermal velocity of electrons is square, where I have written v_{th} is equal to T_e / m under root.

Here, please remember minus e is the electron charge, n_0 is the equilibrium value of electron density, k is the propagation constant of the wave, m is the mass of the electron, v_{th} is the thermal velocity of the electrons. This n_1 will be out of phase by π with respect to ϕ if this term is smaller than ω^2 , on the other hand if $k v_{th}$ is bigger than ω . I can ignore this term and response becomes very simple in the particular case or $k v_{th}$ much bigger than ω for low frequency response this is positive and this reduces to simply.

Let me write this, for low frequencies you get n_1 is equal to $n_0 e \phi k^2$ will cancel out and upon T this is called adiabatic response. and you may recall this ω^2 terms comes from Δv by Δt in the equation of motion called inertia term and this comes because of the pressure term.

So, at low frequencies or when ω by k the phase velocity of the wave is less than thermal velocity of electrons, in that case the electrons respond almost instantaneously to the field of the electro static wave this is called Boltzmann distribution they all obey some sort of a Boltzmann distribution or their response is called adiabatic response.

Quickly, where the potential is large electrons will move there and so on this is the n_1 is bigger where ϕ is bigger same phase they oscillate.

But this is a case waves that satisfy this condition are called sound waves or ion acoustic wave but, today I will begin my discussion with a high frequency wave for which ω is bigger than $k v_{th}$ that wave is called **(C)** wave and for that high frequency wave you may note that, if I write down a similar expression for ion density perturbation let me write down that expression I think then you will appreciate it better.

(Refer Slide Time: 29:21)

For ions

$$n_{1i} = \frac{n_0 e k^2 \phi}{m_i (\omega^2 - k^2 v_{thi}^2)}$$

$$\approx \frac{n_0 e k^2 \phi}{m_i \omega^2}$$

$$n_1 = - \frac{n_0 e k^2 \phi}{m (\omega^2 - k^2 v_{th}^2)} \quad \begin{matrix} \omega > k v_{th} \\ n_1 > n_{1i} \end{matrix}$$

NPTEL

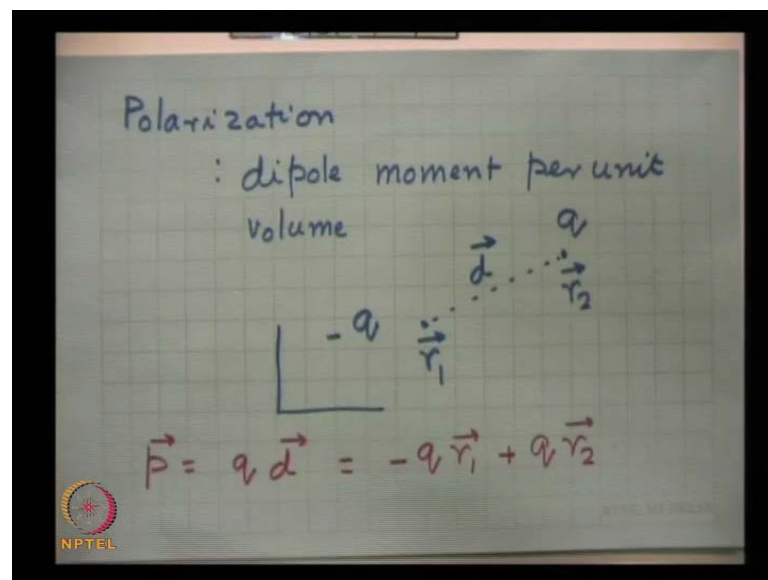

So far, ions the density perturbation for ions would be n_{1i} would be equal to n_0 charge of the ion which I am taking to be singly ionized into $k^2 \phi$ upon mass of the ion into $\omega^2 - k^2 v_{thi}^2$. But thermal velocity of ions is very small as compared to electron thermal velocity so this term is usually very small and you can ignore this, so I can approximate this as $n_0 e k^2 \phi$ upon $m_i \omega^2$. So far, a high frequency wave where n_e and one of electrons is equal to n_1 minus $n_0 e k^2 \phi$ upon $m (\omega^2 - k^2 v_{th}^2)$, because I am choosing this term to be less than ω^2 .

So, numerators of both these terms are equal in magnitude this denominator is small as compared to this denominator, because of mass and ion mass is very heavy. So this term is very large as compared to this term so for high frequency waves or ω bigger than

$k v$ thermal, we have n_1 much bigger than ion density perturbation and hence I can ignore the ion motion.

So, the high frequency waves satisfying this condition for those waves. I can completely ignore the ion density perturbation and electron density perturbation is expressed in terms of ϕ well people like to write down this n_1 in terms of a quantity called susceptibility. So rather before proceeding further, I can write this in a slightly different way density perturbation you know I can talk of a polarization.

(Refer Slide Time: 31:48)

Polarization normally is a quantity that is employed in dielectrics, what does this mean? This is called dipole moment per unit volume **per unit volume** and what is a dipole moment, suppose I have a pair of charges one placed here the other placed there the charge is suppose minus q here and plus q there. The position coordinate of this in a coordinate system suppose this coordinate is r_1 and the coordinate of this point is r_2 . So, in a system if I have two charges minus q and q plus that a distance at positions r_1 and r_2 then the distance between them is called d which is equal to r_2 minus r_1 . And you define the dipole moment of this **(())** of charges v is equal to magnitude of these either of the two charges q multiply by the distance d , starting from the negative charge to positive charge this is the definition of dipole moment. Which, I can also write down simply as product of charge and position coordinate this is minus $q r_1$ plus $q r_2$, if you write down this way this also the same thing, because r_2 minus r_1 is d .

So, this is the same way of writing of dipole moment of an atom. If there are many such particles you just multiply the position coordinate of each particle with the charge of the particle and add like this quantity is called dipole moment per unit volume. Now, in case of plasmas we are talking about charges per unit volume with density n or $n I$, so what I should have.

(Refer Slide Time: 34:26)

$$\vec{P} = n_e(-e)\vec{r}_e - n_o(e)\vec{r}_i$$

$$n_e = n_o + n_i, \quad \vec{r}_e = \vec{r}_i + \frac{\text{disp}}{d}$$

$$\vec{P} = -n_o e \vec{d}, \quad \frac{d}{dt} \text{disp} = \vec{v}$$

So polarization p in plasmas is defined as electron charge is $n e$ for instance and minus e is the electron charge, so this is the density of electrons into charge of each electrons this the charged density per unit volume multiply by the position of the particle.

Now, position of the electrons they are distributed all over, so I should really consider because this is I have to let me call this r_e of electron position and there should be ion position also, because ions are located with density n_0 charge plus e and ion position say r_i , what should I do? Because n_e is equal to n_0 plus n_1 this is the electron density, so n_0 term will cancel out because ions and electrons are the same place or r_i , r_e I can write down volume element position is equal to initial position where ions $(())$ some displacement.

So, just put this displacement equal to d this becomes p is equal to minus $n_1 e$, well actually this is $n_0 e$ into d plus there will be a term which is a product of two small quantities I can ignore that.

Well this is the way one can proceed and what is the displacement? This is related to velocity $d t$ of displacement is equal to velocity, if you work out from there you can find a connection between this dipole moment and density perturbation or velocity perturbation. Well, I just want to write this I do not want to give you a mathematical derivation, I just want to say that one can easily show that the density perturbation.

(Refer Slide Time: 36:56)

$$n_1 = - \frac{n_0 e^2 k^2 \phi}{\epsilon_0 m (\omega^2 - k^2 v_{th}^2)} \frac{\epsilon_0}{e}$$

$$= - \frac{\omega_p^2 \phi}{\omega^2 - k^2 v_{th}^2} \frac{k^2 \epsilon_0}{e}$$

$$= \chi_e \frac{k^2 \epsilon_0}{e} \phi$$

$$\chi_e = - \frac{\omega_p^2}{\omega^2 - k^2 v_{th}^2} \quad \vec{P} = \epsilon_0 \chi_e \vec{E}$$

e^- Susceptibility

That I get n_1 which I obtained as minus $n_0 e k^2 \phi$ upon m into ω^2 minus $k^2 v_{th}^2$. if I multiply this equation by e up and e down and ϵ_0 up and down then this can be written as so you multiply e here, and divided by e here multiply by ϵ_0 here and multiply by ϵ_0 there then you know that $n_0 e^2 k^2 \epsilon_0$ is ω_p^2 upon $\omega^2 - k^2 v_{th}^2$ into ϕ the remaining term is $k^2 \epsilon_0$ divided by e , this quantity which is coefficient of ϕ in this first term is called electron susceptibility.

As we will see that, this is dimensionless quantity and susceptibility is also dimensionless quantity. So we have taken care of this extra factor, if I write explicitly so people write this is equal to χ_e into $k^2 \epsilon_0$ by e into ϕ and this susceptibility I have written as minus ω_p^2 upon $\omega^2 - k^2 v_{th}^2$, one can show that the polarization P that I was deriving in the last page is equal to $\epsilon_0 \chi_e E$.

That is why? This constant independent of time and position etcetera, this depends only on electron density in the equilibrium, electron temperature in equilibrium and omega and k of the wave this quantity is a characteristic of a plasma depends on its density and temperature and on wave parameters omega and k.

Similarly, I can write down the density perturbation for ions if it is required, in the present case of high frequency wave when omega is much bigger than k v thermal you do not require there. So, if I know the density perturbation I can go to the wave equation this quantity is known as electron susceptibility.

(Refer Slide Time: 40:14)

The image shows a series of handwritten equations on a grid background, likely from a lecture slide. The equations are:

$$\nabla^2 \phi = \frac{e}{\epsilon_0} n_1$$

$$\phi = - \frac{e}{\epsilon_0 k^2} n_1$$

$$\phi = - \chi_e \phi$$

$$1 + \chi_e = 0 \quad 1 - \frac{\omega_p^2}{\omega^2 - k^2 v_{th}^2} = 0$$

In the bottom left corner of the grid, there is a small circular logo with the text 'NPTEL' below it.

And my wave equation would be or the Poisson equation would be del square phi is equal to e upon epsilon 0 into n 1, this was my Poisson equation if I ignore the ion density perturbation del square. Again I will replace by minus k square, so this becomes phi is equal to minus e upon epsilon 0 into k square n 1 and put the value of n 1 in terms of chi this becomes minus chi e into phi. You may see, the reasoning here that this is a same factor with n1 that was in the expression for n1, in the reverse way so that this cancels out and if I want a non trivial solution then phi will cancel out on both sides and one is should be equal to this or the dispersion relation becomes 1 plus chi e is equal to 0

If, you put the value of χ_e this gives $1 - \omega_p^2 / \omega^2 - k^2 v_{th}^2 / \omega^2 = 0$, you can simplify this and you get the dispersion relation for the langmuir wave or plasma wave.

(Refer Slide Time: 41:52)

$$\omega^2 = \omega_p^2 + k^2 v_{th}^2$$

$$\omega > \omega_p$$

If ion motion is included

$$\omega < k v_{th}$$

only when this happens

$$n_i = -\frac{k^2 e}{\epsilon_0} \chi_i \phi, \quad \chi_i = -\frac{\omega_p^2}{\omega^2}$$

NPTEL

And that is $\omega^2 = \omega_p^2 + k^2 v_{th}^2$. If I plot this plot k here, and ω there **there** is a frequency ω_p the value of ω cannot be less than ω_p , because this is a positive term and the disperse relation goes like this. So, ω increases with k , the minimum value ω can take it ω_p so these high frequency waves can have frequencies only bigger than ω_p . So, this is one branch of electrostatic waves where ion motion is ignored, if we have included the ion motion; if ion motion is included, what do I get? well as I mentioned ion motion will be important only when the electron response is such that ω is less than $k v_{th}$.

So that the electron term is strongly suppressed as compared to ion term only when this happens and in this case what happens? The ion response turns out to be $k^2 e / \epsilon_0 \chi_i \phi$ and ion susceptibility is written as $-\omega_p^2 / \omega^2$, you do not have to include the ion thermal effects, because the ion thermal velocity is very small because of the mass coming in this denominator. So, if I know the this n_i rather this n_i .

(Refer Slide Time: 44:23)

The whiteboard contains the following equations:

$$\nabla^2 \phi = \frac{e}{\epsilon_0} (n_1 - n_{1i})$$

$$\phi = -\frac{e}{k^2 \epsilon_0} \left(\frac{k^2 \epsilon_0}{e} \chi_e \phi + \frac{k^2 \epsilon_0}{e} \chi_i \phi \right)$$

$$1 + \chi_e + \chi_i = 0$$

$$1 - \frac{\omega_p^2}{\omega^2 - k^2 v_{th}^2} - \frac{\omega_{pi}^2}{\omega^2} = 0$$

An NPTEL logo is visible in the bottom left corner of the whiteboard image.

So, if I know the electron and ion density perturbations then the Poisson equation becomes $\nabla^2 \phi$ is equal to e upon ϵ_0 , n_1 minus n_1 of ions put these replaced by minus k^2 this becomes ϕ is equal to e upon $k^2 \epsilon_0$, the negative sign and this becomes $k^2 \epsilon_0$ by E into χ_e into ϕ and this also becomes plus then because 1 minus is there 1 is in this becomes $k^2 \epsilon_0$ by e χ_i into ϕ .

All this will cancel out and the dispersion relation is $1 + \chi_e + \chi_i = 0$, if I put these values this becomes $1 + \frac{\omega_p^2}{\omega^2 - k^2 v_{th}^2} - \frac{\omega_{pi}^2}{\omega^2} = 0$, this is minus here I am **sorry** this is minus sign upon ω^2 is equal to 0 .

But, as I mentioned this term is very huge as compared to this term unless this is negligible as compared to this, so I ignore this so suppress this term as compared to this one, when this is comparable to this term the wave is called Langmuir wave, that I have already discussed, so only when this is less than this.

(Refer Slide Time: 46:19)

$$\omega^2 = \frac{\omega_{pi}^2}{1 + \frac{\omega_p^2}{k^2 v_{th}^2}}$$

$$\frac{\omega_p^2}{k^2 v_{th}^2} = \frac{n_0 e^2}{m \epsilon_0} \frac{m}{k^2 T_e} = \frac{n_0 e^2}{m_i \epsilon_0} \frac{m_i}{k^2 T_e}$$

$$= \frac{\omega_{pi}^2}{k^2 c_s^2}, \quad c_s \equiv \sqrt{T_e / m_i}$$

This ion term is important and in that case this equation gives you omega square is equal to omega p i square upon 1 plus omega p square upon k square v thermal square. but you know omega p square upon k square v thermal square is the same thing as n 0 e Square upon m epsilon 0, this is for omega p square k square is there and v thermal square is T e upon m, what you can do? m will cancel with this m you can write this as same thing e Square upon m i epsilon 0 into m i upon k square T e, because m i will cancel this m i so they are equal exactly same this quantity I call as ion plasma frequency square k square is there T e upon m i the ratio of electron temperature to ion mass.

This quantity is denoted as C s square, so C s is equal to T e upon m i this is known as the sound speed plus we shall learn about it why this is called sound speed I am just defining a constant at the moment T e upon m i under root as C s. So, if I use this omega p square by k square v thermal square as this quantity when omega square this dispersion relation for the ion acoustic wave.

(Refer Slide Time: 48:15)

$$\omega^2 = \frac{k^2 c_s^2}{1 + k^2 c_s^2 / \omega_{pi}^2}$$

For $k c_s \ll \omega_{pi}$
 $\omega \approx k c_s$, $v_p = \frac{\omega}{k} = c_s$ LW

$k c_s \gg \omega_{pi}$
 $\omega = \omega_{pi}$ IA

Can be written as you can rewrite this slightly in a different way ω is equal square is equal to k square C s square upon $1 + k$ square C s square upon ω square, for $k C$ s less than ω you can ignore this second term in the denominator and so for $k C$ s much less than ω this ω is nearly equal to $k C$ s. This is a linear relationship between ω and k and the phase velocity is ω by k equal to C s sound velocity.

So, this the wave whose phase velocity at low frequency is sorry this is sorry this is wrong I am **sorry** I made a mistake this is ω_{pi} square hence ω_{pi} . So, when $k C$ s is much less than ω_{pi} , the frequency of the wave is like $k C$ s and phase velocity is like C s but, when $k C$ s is large. So as $k C$ s becomes bigger than ω_{pi} ω approaches equal to ω_{pi} ion plasma frequency.

So, let me plot a graph here, I am plotting k here and ω there and ion plasma frequency is here, please remember ion plasma frequency is very small as compared to electron plasma frequency. So these waves always have a frequency less than ω_{pi} that is dispersion goes like this and electron plasma wave was ω_p was much higher here the dispersion relation was like this.

So, this branch this lower branch is called ion acoustic wave, and this is called Langmuir wave there is a big forbidden gap between ω_{pi} and ω_p , the ion plasma frequency and electron plasma frequency there is no electrostatic wave possible. This is a very important consequence of ignoring thermal motions, ion acoustic wave will not

exist if there is no thermal motion, because the electron response will always be more dominant than the ion response.

So, thermal motion is mandatory for the ion acoustic wave as far as the Langmuir wave is concerned. If thermal motion is not there then ω is always equal to ω_p . There is no k dependence, so k dependence of ω of Langmuir wave arises because of temperature so temperature provides k dependence to Langmuir wave and it also makes the existence of ion acoustic wave possible. Now, let me mention a few words about the energy carried by these waves in my next lecture, I will deduce an expression for energy density but, today I will presume it.

Power flow of EM waves

$$\vec{S} = \vec{E} \times \vec{H}$$

$$\vec{J} = \nabla \times \vec{H} - \frac{\partial \vec{D}}{\partial t}$$

$$\vec{J} \cdot \vec{E} = \vec{E} \cdot \nabla \times \vec{H} - \vec{E} \cdot \frac{\partial \vec{D}}{\partial t}$$

$$= -\nabla \cdot \vec{S} - \frac{\partial}{\partial t} \left(\frac{1}{2} \epsilon E^2 + \frac{1}{2} \mu H^2 \right)$$

NPTEL

You know, for electromagnetic waves we know power flow of EM waves is given by pointing vector. S is equal to v cross H for electrostatic wave there is no magnetic field, H is not there, so this kind of pointing vector does not exist, does it mean that the waves do not carry any energy or momentum, this is not true. After all this S is equal to E cross H was deduced from Maxwell's equations, how to deduce this? You write down J is equal to from forth Maxwell's equation is equal to curl of H minus δD by δt .

And then you dot this equation with E , J dot E and you will get E dot curl of H minus E dot δD by δt and then you interpret this as the energy absorbed by electrons of charged particles per unit volume and then you write this curl of E dot curl of H in terms of a quantity called this becomes divergence of S , and then there is a term which gives

you like $\Delta \Delta t$ actually this is minus here and $\Delta \Delta t$ of half $\epsilon_0 E^2$ plus half $\mu_0 H^2$, this is the way you interpret this saying that this is the pointing flux the amount of energy flowing per unit area per unit time, this is how you do it.

The entire $\langle \langle \rangle \rangle$ is in the interpretation of $\mathbf{J} \cdot \mathbf{E}$ we have seen that in a collisionless plasma \mathbf{J} equal to $\sigma \mathbf{E}$ but, σ is imaginary then this quantity does not represent a power dissipation, so it depends on the interpretation of this quantity. If, we ignore the interpretation of this quantity properly proper interpretation, if you ignore then you get a wrong result.

So, the waves which do not have a magnetic field by a proper interpretation of $\mathbf{J} \cdot \mathbf{E}$ term you should be able to see, that the energy contained in **in** the electric field is not half $\epsilon_0 E^2$ for electrostatic wave H is 0 so this term does not exist but, this is $\langle \langle \rangle \rangle$ definition. rather in general in a dispersive medium where permittivity depends on frequency in that medium.

(Refer Slide Time: 54:46)

The whiteboard contains the following handwritten equations and text:

$$W_E = \frac{1}{2} \epsilon_0 \frac{\partial (\omega \epsilon_{eff})}{\partial \omega} E^2$$

$$\vec{S} = W_E \vec{v}_g, \quad \vec{v}_g = \frac{\partial \omega}{\partial \vec{k}}$$

$$\omega^2 = \omega_p^2 + k^2 v_{th}^2$$

$$2\omega \frac{\partial \omega}{\partial k} = 2k v_{th}^2 \Rightarrow v_g = \frac{v_{th}^2}{\omega/k}$$

$\hbar \omega, \quad \hbar \vec{k}$ Plasmon

NPTEL logo is visible in the bottom left corner of the whiteboard image.

The energy contained in the electric field is denoted as W_E is equal to half ϵ_0 into $\Delta \Delta \omega$ of $\omega \epsilon_{eff}$ into E^2 rather than calling this half ϵ_0 into $\epsilon_{eff} E^2$, this is the right definition and when you use this we shall derive this expression next time then we will see that the energy contained with the wave is this quantity and energy propagating with the wave is W_E into v_g this is the equivalent pointing flux for a electro static wave.

And group velocity is $\Delta \omega$ by Δk magnitude wise, vector wise like this. Now, we have seen that for a plasma wave ω^2 is equal to $\omega_p^2 + k^2 v_{th}^2$. So if I want to obtain the group velocity how much that would be you differentiate ω^2 w.r.t k , so you will get $2\omega \Delta \omega$ by Δk is equal to $2k v_{th}^2$.

So, this is the group velocity so you get group velocity is equal to v_{th}^2 upon ω/k this is the phase velocity v_{ph} , you can obtain from this relation and write this there so group velocity will vanish if v_{th} is not there. So, it is the thermal motion which gives rise to finite energy propagation or finite improved velocity if this is not there pointing flux will be 0. So, thermal motions play very important role in energy transfer with plasma waves, plasma waves carry energy as well as momentum each quantum of plasma wave is called Plasmon with energy $\hbar \omega$ and momentum $\hbar k$ called Plasmon.

The beauty of these waves is, in a thermalized plasma like this their dispersion relation is like this k can be very close to 0 or to be finite if it is very close to 0, the phase velocity will be very large they can have phase velocity close to c or close to a few times thermal velocity but, when they become very close to thermal velocity when the phase wave velocity becomes very close to thermal velocity a very important phenomenon occurs and that is called the phenomenon of Landau damping that we can discuss on the basis of kinetic theory but, prior to discussing that I would like to discuss the phenomenon of two stream instability, because that will give you an insight into the Landau damping but, that is a different matter.

For today, it will suffice to say that a plasma wave is strongly influenced by these thermal motions of electrons, they provide a group velocity these waves can have phase velocity close to c , and these waves can trap electrons and accelerate them to velocities close to c . And this is the basic mechanism of laser based electron acceleration. I think, I would like to stop here, for today, and then we will discuss other issues in next lecture. Thank you.
