Lecture No. # 36
Landau Damping and Growth of Waves (contd.)

(Refer Slide Time: 00:34)

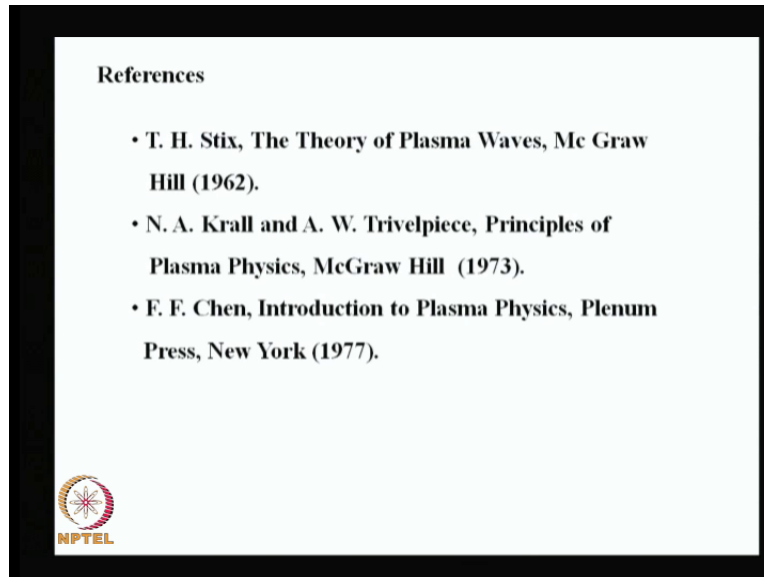

We will discuss

- Landau damping of plasma wave
- Landau damping of ion acoustic wave
- Bump in tail instability
- Ion acoustic instability

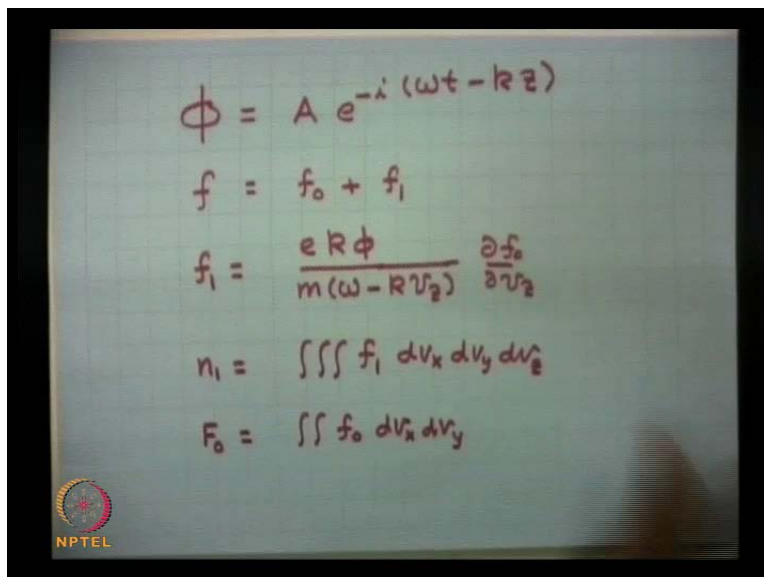

Today, we will continue talking about Landau damping and growth of waves in plasmas. We shall discuss Landau damping of a plasma wave, then Landau damping of ion acoustic wave, bump in tail instability and ion acoustic instability.

(Refer Slide Time: 00:48)

The references for today's talk would be three books; one by Stix, another one by Krall and Trivelpiece, and third one by F.F.Chen.

(Refer Slide Time: 01:11)

Let me recapitulate, what we were doing last time. We were considering the response of a plasma to a wave of potential ϕ is equal to A exponential minus i ωt minus $k z$. And what we have done was that we said that in the presence of this, the distribution function of electrons

can be written as f_0 plus f_1 ; f_0 is the equilibrium distribution function and f_1 is the modification caused by the plasma wave of potential ϕ . Then, we solve the Vlasov equation for f_1 and we obtained an expression for the perturbed distribution function, which is equal to $e k \phi$ divided by $m \omega - k v_z$ multiplied by δf_0 by δv_z , here minus e is the electron charge and m is the electron mass. One may note here that those particles for which v_z is equal to ω upon k , the denominator will go to 0 and they are called the resonant particles. The perturbation and f_1 will be very large and these are the particles which give rise to resonant wave particle interaction and are responsible for damping or growth of waves.

Then, we introduced the density perturbation, which essentially is a triple volume integral of f_1 , this f_1 into $d v_x d v_y$ and $d v_z$. At this stage, we introduced a quantity called one dimensional distribution function because when we integrate this f_1 respect to v_x and v_y , where the derivative of f_0 comes only through v_z and there is no v_z dependence here. **Sorry no**, v_x and v_y dependence here. So, this can be easily integrated and one introduced a quantity called one dimensional distribution function f_0 , which was essentially integral double integral of f_0 over $d v_x$ and $d v_y$. So, this f_0 is a function of primarily of v_z , only of v_z rather.

(Refer Slide Time: 04:03)

$$n_1 = \frac{k^2 \epsilon_0}{e} \chi_e \phi$$

$$\chi_e = - \frac{e^2}{m \epsilon_0 k^2} \int_{-\infty}^{\infty} \frac{\partial F_0 / \partial v_z}{v_z - \omega/k} \cdot d v_z$$

Maxwellian distribution

$$F_0 = \frac{n_0}{n^{3/2} v_{th}^3} e^{-v_z^2 / v_{th}^2}$$

$$\zeta(\zeta) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} \frac{e^{-p^2}}{p - \zeta} dp$$

Imp \rightarrow $\text{Re } p$

And in terms of this, one can obtain n_1 and we said that I will write n_1 as $k^2 \epsilon_0$ upon e into χ_e into ϕ , ϵ_0 is called free space permittivity and χ_e is called the

susceptibility, let me put a subscript e. I think we put a subscript e because this designates electron susceptibility and the expression for χ_e then, was is equal to minus e square upon m epsilon 0 k square integral minus infinity to infinity delta F 0 by delta v z divided by v z minus omega by k and this was d v z already, I have written. **Sorry**, d v z I have to write, d v z.

This is the expression we had written last time and for the case of Maxwellian distribution function, Maxwellian distribution means I choose F 0 as density of electrons per unit volume divided by pi to the power 3 half, **sorry** 1 half multiplied by v thermal into exponential minus v z square by v thermally square. So, for this case we found that susceptibility becomes simple, is expressible into z functions and z function I defined as z of xi is equal to 1 upon root pi, this goes from minus infinity to infinity exponential minus p square upon p minus xi d p.

And the evolution of this integral has to be done following the Landau's prescription. So, what we do here, if I plot real v z, we treat or p we treat as a complex quantity. So, real part of p be plot here and imaginary part of p, we plot here and then we carry out the integral along the horizontal axis because there is a pole at xi. So, this is the pole at xi, but the integral has to be like this. It has to go round the pole. So, this is the integral line integral. So, following Landau's prescription, one can evaluate this integral and people have indeed evaluated this integral, free run **(C)** have carried out this study. z function always has a contribution due to this pole.

(Refer Slide Time: 07:42)

Handwritten mathematical notes on a whiteboard:

$$\xi \gg 1, \quad \xi = \omega / kv_{th}$$

$$Z(\xi) \approx -\frac{1}{\xi} - \frac{1}{2\xi^3} - \frac{3}{4\xi^5} + i\sqrt{\pi} e^{-\xi^2}$$

$$\xi \ll 1$$

$$Z(\xi) = -2\xi \dots + i\sqrt{\pi} e^{-\xi^2}$$

$$\chi_e = \frac{2\omega_p^2}{k^2 v_{th}^2} \left[1 + \frac{\omega}{kv_{th}} Z\left(\frac{\omega}{kv_{th}}\right) \right]$$

$$1 + \chi_e = 0$$

NPTEL logo is visible in the bottom left corner of the whiteboard image.

And in the limit, when ξ is much bigger than 1, this becomes, this z function of ξ is approximately equal to minus 1 upon ξ minus 1 upon 2ξ cube minus 3 upon 4 ξ to the power 5 plus $i \sqrt{\pi}$ into exponential minus ξ square. This is the expression for ξ . In the limit, when ξ is much bigger than 1 and in the other limit, when ξ is much less than 1. You can write z approximately equal to minus 2 ξ etcetera plus $i \sqrt{\pi}$ exponential minus ξ square and this factor is nearly 1. So, this like $i \sqrt{\pi}$. Well, in terms of this z function the plasma susceptibility was susceptibility χ_e , we had written was, is equal to $2 \omega_p^2$ upon $k^2 v_{th}^2$ thermally square 1 plus ω upon $k v_{th}$ into z function of ω upon $k v_{th}$ and the dispersant relation was for the plasma wave 1 plus χ_e is equal to 0.

Now, I would like to simplify this by presuming that the phase velocity of the wave is bigger than v_{th} . So, ω by k is v_{th} is greater than 1. ξ implies here is the argument of z function, which is ω by $k v_{th}$. So, well let me mention here that ξ I am talking about is ω upon $k v_{th}$. So, in the limit, when ω by $k v_{th}$ is bigger than 1, I can use this expansion and when I carryout this expansion, χ_e turns out to be rather simple. Let me write down this expression or rather this expression I will write down.

(Refer Slide Time: 10:31)

The image shows a whiteboard with handwritten mathematical derivations and two small graphs. The equations are as follows:

$$1 - \frac{\omega_p^2}{\omega^2} - \frac{\omega_p^2}{\omega^2} \frac{1}{2} \frac{k^2 v_{th}^2}{\omega^2} + i \sqrt{\pi} \frac{2 \omega_p^2}{k^2 v_{th}^2} e^{-\omega^2 / k^2 v_{th}^2} = 0$$

$$v_{th} = \sqrt{2T_e/m}$$

$$\omega = \omega_r + i \Gamma$$

$$\omega_r^2 = \omega_p^2 + \frac{1}{2} k^2 v_{th}^2$$

$$\Gamma = \sqrt{\pi} \frac{\omega_p^2 \omega}{k^3 v_{th}^3} e^{-\omega_r^2 / k^2 v_{th}^2}$$

Below the equations, there is a red note: $\omega_r^2 \gg k^2 v_{th}^2$.

Two small graphs are shown on the right side of the whiteboard:

- The top graph plots ω versus k . A horizontal dashed line is drawn at ω_p on the vertical axis. A solid curve starts from the origin and increases, crossing the ω_p line.
- The bottom graph plots Γ versus k . The vertical axis is labeled $\frac{\omega_p^2}{v_{th}}$. A solid curve starts from the origin and increases, showing a non-linear relationship.

So, if I write this, this takes the following form. 1 minus ω_p^2 by ω^2 minus ω_p^2 by ω^2 into $\frac{1}{2} k^2 v_{th}^2$ upon ω^2 plus $i \sqrt{\pi}$ $\frac{2 \omega_p^2}{k^2 v_{th}^2}$ exponential minus $\omega^2 / k^2 v_{th}^2$ is equal to 0.

plus the imaginary part $i \sqrt{\pi} \omega^2 \omega_p^2$ divided by $k^2 v_{\text{thermal}}^2$ into exponential minus ω^2 by $k^2 v_{\text{thermal}}^2$ is equal to 0. I forgot to mention that v_{thermal} is related to electron temperature by this relation, $\sqrt{2 T_e / m}$, where T_e is the electron temperature, m is the electron mass.

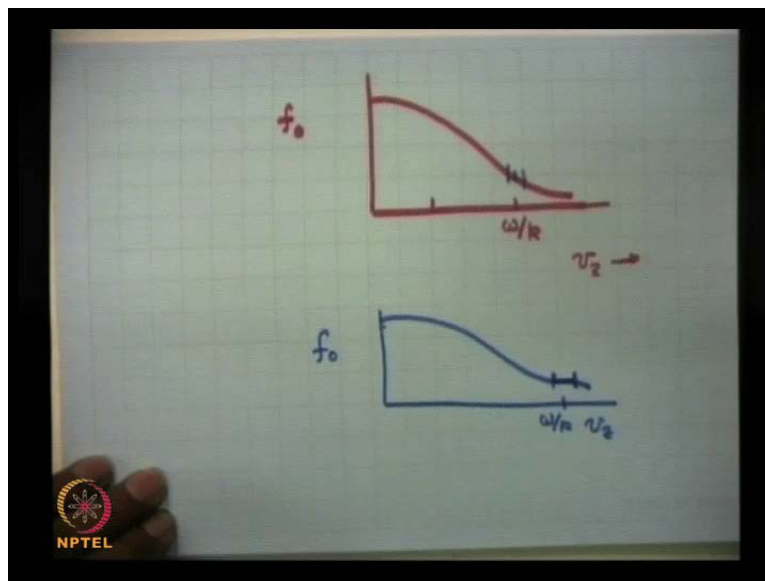

Well, if ω is substantially bigger than ω_p , this term is quietly small, but it still significant. So, this is a equation, which you can solve for ω and I can write down ω is equal to a real part of ω plus imaginary part of ω , but this turns out to be negative sign. So, I write down simply minus here into γ and presuming that ω_r is bigger than γ . You can equate the real imaginary parts of this term to 0 separately. So, real part of ω turns out to be ω_r turns out to be equal to ω_p^2 , this is equal to this square plus $3/2 k^2 v_{\text{thermal}}^2$, this if you equate this equal to 0, you will get ω_r actually. This expression you will get.

And nearly, approximately because I am taking this term to be small as compare to this one and imaginary part turns out to be γ , which we call the damping rate, it turns out to be $\sqrt{\pi} \omega_p^2$ into ω divided by k , this should be $k^2 v_{\text{thermal}}^2$. Actually, this is cube here and this is $k^3 v_{\text{thermal}}^3$ multiplied by exponential minus ω^2 upon $k^2 v_{\text{thermal}}^2$. You may note here that the damping is a function of frequency **frequency**, this ω is ω_r actually. But we can suppress the subscript r implying that it is implicit. So, the frequency you may note here, if I plot ω_r , ω_r as a function of k . Suppose, ω_p is here, at k is equal to 0, ω equal to ω_p and that is we plot here, this will go something like this. This sort of variation you will get.

Now, if you are too close to ω_p , then k will be very small and when k is a small this quantity is very large. So, damping rate will be negligible. So, if I plot here damping rate, damping rate, I will call as γ as a function of k because when k changes, ω correspondingly **change** changes. So, use a proper value of ω from this graph and use this here, then plot γ has a function of k . You will find that when k becomes comparable to ω_p by v_{thermal} . In that case, this term is nearly unity and this is huge. So, damping rate is very tiny and becomes very large, when k becomes comparable to ω_p by v_{thermal} . Suppose, ω_p by v_{thermal} is here.

This is ω/k upon v_{thermal} . I am varying this quantity k here. So, this is the point where ω/k becomes ω/k upon v_{thermal} . The damping is very huge here. So, it starts from here and then it increases rapidly. The scale for this is different than the scale for ω , but this could be quite large. Obviously, my approximation fails here; it is not valid up to this point. It is valid only up to somewhere here, because as I mention to you, I have already assumed that ω is bigger than $k^2 v_{\text{thermal}}^2$. So, this was my assumption. So, I cannot go close to unity here, it should be here may be half or something one-third. So, but it still the damping is strong as you move to shorter wave length or larger values of k and this is a collision less damping. It will be useful to, look at the wave number of phase velocity of the wave over the distribution function. If I plot here f_0 as a function of v , for Maxwellian plasma this goes like this.

(Refer Slide Time: 16:44)

This is my Maxwellian distribution function and my thermal velocity is somewhere here. This is my thermal velocity somewhere here and my phase velocity of wave is somewhere here. So, suppose my ω/k is here, depending on the value of k . This is these are the particles which are called resonant particles. So, in this neighborhood you are expecting resonant interaction of waves with particles, this is the range. What will happen? The particles which are on the left of this ω/k point, these particles are moving slower than the wave. The particles which are ahead of it, they are moving faster initially. But as I mentioned that as the wave grows these

particles lose energy. The faster particles lose energy and the slower particles gain energy. Consequently, particles from here to here move and there is a plateau created there.

So, the distribution function appears becomes like this. f_0 if I plot, v_z here the distribution function I have plotted here. So, in this a some plateau is created here, this is the range v_g . **Sorry**, ω/k is here. So, a plateau is created horizontal becomes flat. Once this becomes flat, then there is no growth. Because there is no slope in f_0 . So, Landau damping will be a transient phenomenon. After a little while, when this flattens, there will be no damping. Obviously, if the electron-electron collisions restore the distribution function to be Maxwellian, then this will be an ongoing process.

So, laminar waves will be damped up to a point and beyond that point the damping will stop. When the particle distribution function has become like this, until or unless there is a restoration of Maxwellian form of the distribution function. It is collision new. So, this is from physics we have learnt. Obviously, the waves of larger k , this ω/k point will be closer here and then, the number of particles in the distribution function are more. So, there are more and more resonant particles and there will be a stronger damping. So, when ω/k is very large. When k is very tiny, then there is hardly any particles and there is very little damping of the waves. So, one can see this.

(Refer Slide Time: 19:51)

Ion Acoustic wave

$$\omega = \frac{k c_s}{(1 + k^2 c_s^2 / \omega_{pi}^2)^{1/2}}$$

$$c_s = \sqrt{T_e / m_i}$$

$$\omega_{pi} = (n_0 e^2 / m_i \epsilon_0)^{1/2}$$

$$\omega < \omega_{pi}$$

$$v_{ph} = \frac{\omega}{k} < c_s$$

The graph shows angular frequency ω on the vertical axis and $k c_s$ on the horizontal axis. A horizontal line is drawn at $\omega = \omega_{pi}$. A curve starts at the origin, rises to meet the horizontal line at ω_{pi} , and then continues as a horizontal line for larger values of $k c_s$.

Now, let me examine the ion acoustic wave in the presence, well with kinetic effects. So, ion acoustic wave from fluid theory, we had learnt that this is a wave of frequency ω is equal to $k c_s \sqrt{1 + \frac{k^2 c_s^2}{\omega_{pi}^2}}$ to the power half, where c_s is under root of T_e upon m_i , where m_i is the ion mass and ω_{pi} is the ion plasma frequency, which is defined as $n_0 e^2$ upon $m_i \epsilon_0$ under the root. So, a wave of frequency ω with wave number k will have a phase velocity ω by k , which is less than c_s , depends on how close $k c_s$ is to ω_{pi} but the highest value of ω is less than ω_{pi} . So, if I plot a graph here ω versus $k c_s$ and suppose, ω_{pi} is here, then this goes like this. It saturates. But please remember, in the case of ion acoustic wave the velocity is much less than the electron thermal velocity, 50, 60 times or 100 times a smaller.

However, the ion velocity may be comparable to the velocity of the wave. Especially, if my k is large, then ω by k could be significantly smaller as compare to c_s . When $k c_s$ becomes comparable to ω_{pi} , there is a significant reduction. So, the phase velocity of this wave v_{phase} , which is defined as ω by k is less than c_s , because there is a factor underneath. So, it is possible that larger k waves will have a thermal velocity comparable to ion thermal velocity. Because the velocity is if T_e is T_i are same, then thermal velocity will comparable to c_s and the wave will be strongly damped. So, here the damping is expected to come from the ions. So, what you do? You look at the same expression.

(Refer Slide Time: 22:46)

$$\chi_e = \frac{2 \omega_p^2}{k^2 v_{Th}^2} \left[1 + \frac{\omega}{k v_{Th}} Z \left(\frac{\omega}{k v_{Th}} \right) \right]$$

$$\approx \frac{2 \omega_p^2}{k^2 v_{Th}^2} = \frac{\omega_{pi}^2}{k^2 c_s^2}$$

$$\chi_i = \frac{2 \omega_{pi}^2}{k^2 v_{Thi}^2} \left[1 + \frac{\omega}{k v_{Thi}} Z \left(\frac{\omega}{k v_{Thi}} \right) \right]$$

$\omega / k v_{Thi} > 1$

$$\chi_i \approx -\frac{\omega_{pi}^2}{\omega^2} + i \frac{2 \omega_{pi}^2}{k^2 v_{Thi}^2} \sqrt{\pi} \frac{\omega}{k v_{Thi}} e^{-\omega^2 / k^2 v_{Thi}^2}$$

For as we had seen for the electron susceptibility, you can write down the expression for ion susceptibility. Electron susceptibility we had written was $2 \frac{\omega_p^2}{k^2 v_{th}^2} \frac{1}{1 + \frac{\omega}{k v_{th}}}$ of electrons plasma dispersion function of $\frac{\omega}{k v_{th}}$, but **we are** we are considering the limit when ω is much less than $k v_{th}$, then this quantity is negligible. So, this is primarily equal to $2 \frac{\omega_p^2}{k^2 v_{th}^2}$ and this you can easily see, is equal to $\frac{\omega_p^2}{k^2 c_s^2}$, because ω_p^2 is $\frac{q^2 n}{m}$, 1 upon mass, v_{th}^2 also continuous 1 upon mass and it cancel out.

So, whether you put a ω_p or ω_{pi} or c_s the same thing happens. So, this is the value of χ_e . How about the ion susceptibility? Ion susceptibility χ_i is by similarity $2 \frac{\omega_{pi}^2}{k^2 v_{thi}^2}$ where, ω_{pi} is the ion plasma frequency upon $k^2 v_{thi}^2$ and then this becomes $1 + \frac{\omega}{k v_{thi}}$ of ions Z function of $\frac{\omega}{k v_{thi}}$ of ions. Here, I am assuming the plasma to be Maxwellian.

This term again here, for sound waves we are expecting $\frac{\omega}{k v_{thi}}$ to be bigger than 1. So, in the large amplitude approximation I can expand this plasma dispersion function Z function and in that case, χ_i turns out to be approximately equal to $-\frac{\omega_{pi}^2}{\omega^2}$ that is nearly the real part and imaginary part is simply is equal to $+\frac{2 \omega_{pi}^2}{k^2 v_{thi}^2} \frac{i \sqrt{\pi}}{\omega_{pi}}$. So, I will put here, $i \sqrt{\pi} \frac{\omega_{pi}}{\omega}$ and exponential minus $\frac{\omega_{pi}^2}{k^2 v_{thi}^2}$. Well so, χ_i has this is the ion susceptibility, this not the imaginary part. This is real part and a imaginary part. Real part of this and χ_e will determine the real frequency and this will give rise to damping of the wave.

(Refer Slide Time: 26:21)

$$1 + \chi_e + \chi_i = 0$$

$$\phi = A e^{-i(\omega t - k z)}$$

$$1 + \frac{\omega_{pe}^2}{\omega^2 - k^2 c_s^2} - \frac{\omega_{pi}^2}{\omega^2} + i \sqrt{\pi} \frac{2 \omega_{pe}^2 \omega}{k^2 v_{th,e}^2 R v_{th,i}^2} = 0$$

$$\omega = \omega_r - i \Gamma$$

So, let me write down the dispersant relation. The dispersant relation for the sound wave is 1 plus chi e plus chi i equal to 0. chi i essentially is characterizing the perturbation in the electron density, then you multiply this chi by phi and this characterizes the modification in the or perturbation in the ion density by the wave and wave we are considering like this, A exponential minus i omega t minus k z. So, this is the dispersant relation for the sound wave or ion acoustic wave and this turns out to be 1 plus omega p i square upon omega, **sorry** k square c s square, this is the electron susceptibility and ion susceptibility is omega p i square upon omega square plus i root pi and then, you get 2 omega p i square upon k square v thermal i square omega upon k v thermal i multiplied by exponential minus omega square upon k square v thermal i square.

The real is equal to 0. If I forget this, I get the real part of frequency from here. But when this is included, I can write down omega is equal to omega real minus i times some damping rate, omega r just when obtain from here is the same as I have given before by fluid theory. But this is the additional term that you get because of damping due to ions.

(Refer Slide Time: 28:37)

Let me write down the explicit expression for ω_r and the damping rate. ω_r is $\frac{kc_s}{\sqrt{1 + k^2 c_s^2 / \omega_{pi}^2}}$ and damping rate turns out to be $\sqrt{\pi} \frac{\omega^4}{k^3 v_{th,i}^3} e^{-\omega^2 / k^2 v_{th,i}^2}$. This is called ion damping. So, your ϕ is the amplitude of the wave, $|\phi|$ if you plot will go as $e^{-\Gamma t}$. So, it will damp out. Now, if I plot the distribution function for electrons and ions, what I will get is this. If I plot here v_z and put the distribution function for electrons and ions separately, the ion distribution function will be like this. Let me graph by different color. The ion distribution function will be like this and the electron distribution function will be like this. Let me write it by different color and my wave velocity is somewhere here; ω/k is somewhere here.

So, the slope of the electron distribution function is very tiny and that does not give rise to any damping of waves. But if the slope of the ion distribution function, this is ions and this is the electrons, I am plotting here f_0 versus v_z . So, these are the ions here, which are responsible for the damping of the wave. It is very important to know that because especially, when you are talking of wave frequency less than ω_{pi} . So, when ω is significantly less than ω_{pi} may be one-third or less, then ω is around kc_s and this is the factor here, which is responsible for damping. It can become quite large, the damping rate turns out to be, for low frequency range, Γ is of the order of $\sqrt{\pi} \frac{\omega^4}{k^3 v_{th,i}^3} e^{-\omega^2 / k^2 v_{th,i}^2}$.

T_e upon $2 T_i$, this is very important. This tells that unless T_e is much bigger than $2 T_i$, that will be very strong Landau damping of ion acoustic waves.

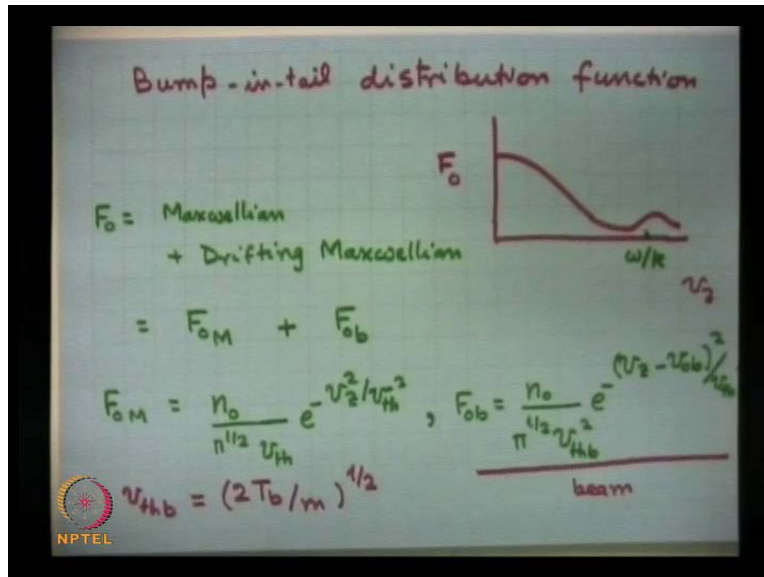

(Refer Slide Time: 31:59)

$$\Gamma \approx \sqrt{\pi} \omega (T_e/2T_i)^3 e^{-T_e/2T_i}$$

$T_e \gg 2T_i$ for weak damping
(non-isothermal plasma)

So, T_e must be much bigger than $2 T_i$ for weak damping of these waves. A plasma in which temperature of electrons is much bigger than the ion temperature is called non isothermal plasma **non isothermal plasma**. But certainly there are plasmas in which temperature of ions is much less than the electron temperature and the ion waves are quite weakly damped. Well this argument is true, when we are talking plasmas with singly ionized ions. In plasmas, where ions are doubly ionized or they have charge $2 e$ or $3 e$ or $4 e$, then this condition changes. But those details are not relevant at the moment. I just wanted to emphasize that thermal effect, because damping of waves. However, with a suitable distribution function, they can give rise to instabilities as well. Physically what would where would you expect the instability. A simple example is the case of a bump in tail distribution. I think I will write this on a separate sheet.

(Refer Slide Time: 34:00)

Let me talk about the bump in tail distribution and the instability or the growth of the wave arising because of that is called bump-in-tail instability, bump-in-tail distribution function. So, suppose we have a plasma, which has a distribution like this. I call F_0 , suppose is a function of v if I plot, I get this kind of thing and this goes like this. So, there is a bump in the tail of the distribution function and in case your wave phase velocity were lying somewhere here, the slope is positive here and the wave velocity, the wave that you are considering has a phase velocity somewhere here, then the slope is positive and the imaginary part of ω will be positive and that will give rise to growth of the wave, because here the number of particles moving faster than ω/k are more and the particles moving slower than ω/k are less. So, more particles are moving faster than the wave and they will give energy to the wave. So, wave will grow.

This kind of distribution you can easily write down as a sum of a Maxwellian distribution plus drift in Maxwellian distribution. So, I can write down this, F_0 is equal to Maxwellian distribution plus drifting Maxwellian and so, I can write down Maxwellian. I will write down simply F_{0M} plus F_{0b} , the drifting Maxwellian I will call F_{0b} , may be something sort of a drifting particles or beam particles moving. Actually, I can call this, actually F_0 either m or F_{0b} , the bulk plasma particles.

So, bulk either the plasma electrons are having Maxwellian distribution and some particles are moving with drifting Maxwellian. So, let me write down these expressions. Maxwellian distribution function in one dimension, I can write down as $n_0 \pi^{-1/2} \exp(-v^2/v_{th}^2)$. So, these are my electrons of the bulk **bulk** electrons of the plasma, but there are some tail electrons, I will call them F_0^b . Suppose, this is equal to $n_0 \pi^{-1/2} \exp(-v^2/v_{th}^2)$, their thermally spread of energy of velocity is suppose less, v_{th}^b is the thermal spread, exponential minus v^2 minus v_0^b square divided by v_{th}^b square.

So, I am writing two distribution functions, sum of 2. This is Maxwellian from here to here. This as a peak at v^2 equal to 0 but this is has a peak at v^2 is equal to v_0^b . So, this tense of the peak from this point is v_0^b . And v_{th}^b is called the, is I can write down v_{th}^b thermal velocity of beam electrons, or drifting electrons, which I can define as $\sqrt{2 T_e / m}$ but T_e and T_b could be very different. So, this is the beam part, this is the bulk part, bulk electrons or plasma electrons. If I use this in the original expression for density perturbation, you get the density perturbations.

(Refer Slide Time: 39:11)

$$\chi_e = \chi_M + \chi_b$$

$$n_1 = \frac{k^2 \epsilon_0}{e} \chi_e \phi$$

$$\chi_M = \frac{2 \omega_p^2}{k^2 v_{th}^2} \left[1 + \frac{\omega}{k v_{th}} Z\left(\frac{\omega}{k v_{th}}\right) \right] \approx -\frac{\omega_p^2}{\omega^2}$$

$$\chi_b = \frac{2 \omega_{pb}^2}{k^2 v_{thb}^2} \left[1 + \frac{\omega - k v_{0b}}{k v_{thb}} Z\left(\frac{\omega - k v_{0b}}{k v_{thb}}\right) \right]$$

$$v_{0b} \approx \omega/k \gg v_{th}, v_{thb}; \omega_{pb} = \sqrt{\frac{n_{0b} e^2}{m \epsilon_0}}$$

And I can define two quantities. Susceptibility of the electrons turns out to be one comprising the Maxwellian part contribution plus 1 having the beam contribution or drifting Maxwellian

contribution. There are two susceptibilities. Obviously, density perturbation of the whole system is $k^2 \epsilon_0$ upon e into susceptibility of the electrons into χ . So, this χ is a very important quantity. Now, this has a sum of 2 terms. one from Maxwellian electrons and one from drifting Maxwellian electrons called beam electrons and what happens if you work out little bit, just follow the old procedure.

χ_m is the same expression as before, which is $2 \omega_p^2$ divided by $k^2 v_{th}^2$ into $1 + \omega / k v_{th}$ function of $\omega / k v_{th}$, whereas, χ_m becomes χ_b is different, this is $2 \omega_{pb}^2$. I may forgot to mention that the density of electrons that I had written earlier. The drifting electrons may have a different density, I will call $n_0 b$. So, if I take this density $n_0 b$, then the corresponding plasma frequency will be ω_{pb} upon $k^2 v_{th}^2$ of the beam electrons square $1 + \omega / k v_{th}$, this turns out to be $\omega - k v_0 b$ upon $k v_{th}$ of the beam. This is the modification, here is ω only and this is $\omega - k v_0 b$, which is called Doppler shifted frequency of the wave has seen by the particles and this is $\omega - k v_0 b$ upon $k v_{th}$. So, this total susceptibility of electrons has two terms one has a important term with Doppler shifted frequency and the other one has just a frequency ω .

What you can do? For the instability, you are or certainly looking for a case, where beam velocity is more than or comparable to ω / k . But this is much bigger than v_{th} of electrons or v_{th} of the beam electrons that is the case of interest. So, in that limit, this simplifies the great deal. It becomes of the order of $-\omega_p^2 / \omega^2$, simply this term and well actually, let me define ω_{pb} here, this is a important quantity, ω_{pb} is I have defined as $n_0 b$, the drifting electron density, e^2 upon $m \epsilon_0$ under the root.

Please note that, in this limit when the beam velocity is much bigger than the thermal velocity of electrons or the thermal velocities spread of the beam distribution function, in that case I can simplify these two expressions a great deal. So, χ_m turns out to be simply this, χ_b will have a real part plus a imaginary part. The real part will be small as compare to the real part of χ_m , because if the density of beam electrons is small, then I expect this to be a small modification.

But the major contribution will come in the imaginary part. So, this is what I am going to do here.

(Refer Slide Time: 43:56)

The whiteboard shows the following equations:

$$1 + \chi_M + \chi_b = 0, \quad n_{0b} \ll n_0$$

$$1 - \frac{\omega_p^2}{\omega^2} + \frac{2\omega p b}{k^2 v_{thb}^2} i \sqrt{\pi} \frac{\omega - kv_{0b}}{k v_{thb}} e^{-\frac{(\omega - kv_{0b})^2}{v_{thb}^2 k^2}} = 0$$

$$\omega = \omega_p + i\gamma$$

$$\gamma = \sqrt{\pi} \frac{v_{0b} - \omega/k}{v_{thb}} \cdot \frac{\omega p b}{k^2 v_{thb}^2} e^{-\frac{(v_{0b} - \omega/k)^2}{v_{thb}^2}}$$

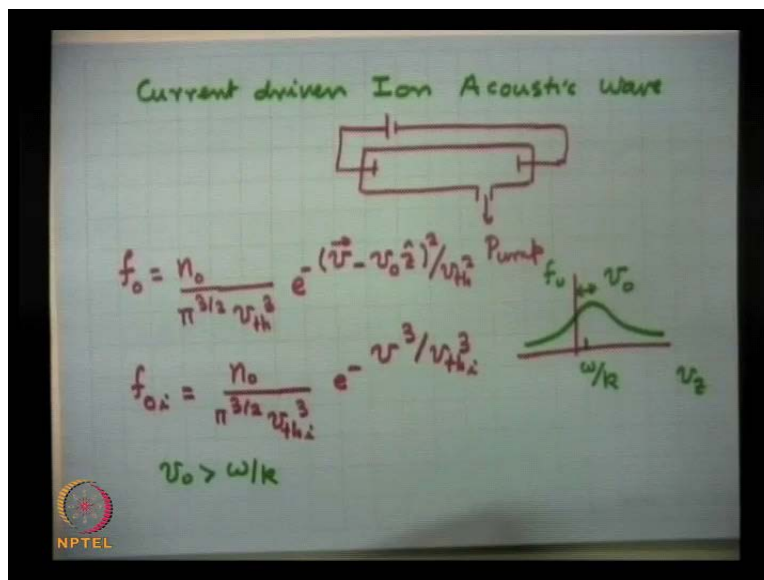

An NPTEL logo is visible in the bottom left corner of the whiteboard image.

I am going to write this imaginary part of this term and my dispersion relation is $1 + \chi_M + \chi_b = 0$ and when you substitute, this becomes $1 - \frac{\omega_p^2}{\omega^2} + \frac{2\omega p b}{k^2 v_{thb}^2} i \sqrt{\pi} \frac{\omega - kv_{0b}}{k v_{thb}} e^{-\frac{(\omega - kv_{0b})^2}{v_{thb}^2 k^2}} = 0$ and due to the second term and χ_b I will simply write only primarily imaginary term, which is equal to $+\frac{2\omega p b}{k^2 v_{thb}^2} i \sqrt{\pi} \frac{\omega - kv_{0b}}{k v_{thb}} e^{-\frac{(\omega - kv_{0b})^2}{v_{thb}^2 k^2}}$. So, this imaginary part because there is a small, well I have written in the limit when beam density n_{0b} is significantly less than the plasma density, in that case real part of the beam contribution to susceptibility can be ignored as compared to the real part of the electron plasma electron contribution.

So, if I ignore this, I get $\omega = \omega_p$, but because of this term ω , I can write down as $\omega = \omega_p + i\gamma$ rather than i times growth rate, just substitute it here and equate the real and imaginary parts, you will get the growth rate. So, growth rate turns out to be equal to, let me just write down this expression. It turns out to be $\sqrt{\pi} \frac{v_{0b} - \omega/k}{v_{thb}} \cdot \frac{\omega p b}{k^2 v_{thb}^2} e^{-\frac{(v_{0b} - \omega/k)^2}{v_{thb}^2}}$, thermal spread in velocity of the electron beam into $\omega_p b$ square upon

$k^2 v_{th}^2 \exp(-v^2/v_{th}^2) - v_0 k^2$ divided by v_{th}^2 . So, whenever the beam velocity is faster than the phase velocity of the wave, more electrons are moving faster than the wave and hence the feed energy into the wave and wave grows. So, this is the growth of the plasma wave, at the expense of energy of the electrons in the tail. So, when there is a bump in the tail, whenever there is a positive slope in the distribution function, you will get this instability. So, plasma waves are often driven unstable, whenever there is a stream of particles moving faster than the thermal velocity of electrons plasma electrons and they create a bump in tail and you get an instability. This is a very important instability in plasmas.

(Refer Slide Time: 47:50)

I would also like to talk to you about another instability; you can drive the ion acoustic waves also unstable by an electron current. So, let me just mention finally, current driven ion acoustic wave or simply ion acoustic instability. This system is rather simple. If you take a plasma somewhere and put two electrodes to which we will be certainly apply potential difference, pass a current in the plasma. The distribution function and there is a pump here, so that you can create a vacuum. So, when you have a plasma at low pressure or gas field in at a low pressure and you created discharge, you produce a plasma but the plasma electrons also have a drift, they are drifting towards the **cathode** anode and the distribution function can be reasonably taken to be Maxwellian, drifting Maxwellian.

So, if I take the plasma electron distribution function like density of electrons n_0 to the power $3/2$ by v thermal cube exponential minus v minus, suppose the electrons are drifting with drift velocity v_0 in the z direction upon v thermal square. So, this is the distribution function, then if you work out the ion distribution function usually in such plasmas can be taken to be f_0 of ions as n_0 upon v thermal of ions cube exponential minus v cube upon v thermal cube of, this is the distribution function of ions, this is i v thermal i .

In that case, the distribution functions will look like this. If I plot here the distribution function for electrons, the electron distribution function will not have a peak here, it has a peak at v equal to v_0 . So, if I plot this as a function of v z and f_0 here, the distribution function for electrons will be like this. So, the peak of the distribution function is somewhere here. So, if I have my ω by k just below the peak, here this peak is shifted at distance v_0 , the distance from here to here is v_0 . So, for v_0 greater than ω by k the slope of the electron distribution function is positive. So, there are more electrons moving faster than the wave and few are moving slower than the wave and there will be a instability. Mathematics is a trivial for this case.

(Refer Slide Time: 51:12)

The image shows a whiteboard with the following handwritten equations:

$$1 + \chi_e + \chi_i = 0$$

$$\chi_e = \frac{2\omega_p^2}{k^2 v_{th}^2} \left[1 + \frac{\omega - kv_0}{k v_{th}} Z\left(\frac{\omega - kv_0}{k v_{th}}\right) \right]$$

$$\approx \frac{\omega_p^2}{k^2 v_{th}^2} \left[1 + i\sqrt{\pi} \frac{\omega - kv_0}{k v_{th}} \right]$$

Below these equations, it is noted that $T_e \gg 2T_i$, and the ion susceptibility is approximated as:

$$\chi_i \approx -\frac{\omega_{pi}^2}{\omega^2}$$

An NPTEL logo is visible in the bottom left corner of the whiteboard image.

Just, let me write down we are having the dispersant relation, 1 plus electron susceptibility plus ion susceptibility equal to 0 and the electron contribution turns out to be χ_e , which is $2\omega_p^2$ upon $k^2 v_{th}^2$ into $1 + \frac{\omega - kv_0}{k v_{th}}$ of the

plasma electrons into z function of omega minus k v 0 upon k v thermal. Since, for sound waves k v thermal is too huge as compare to omega or omega minus k v 0 too huge. So, this quantity, real part of this quantity is negligible imaginary part. So, this becomes approximately equal to, this is becomes equal to omega p i square upon k square v thermal c s square and this becomes 1 plus i root pi into omega minus k v 0 upon k v thermal and if I take ions to be cold, so in the limit when T e is much bigger than 2 T i, ion susceptibility is nearly equal to minus omega p i square by omega square. So, that the ion damping can be ignored. So, in that limit if I just substitute this chi e here and chi i here, you will get instability, whenever v 0 is more than omega by k and it is very trivial to get the dispersant relation.

(Refer Slide Time: 53:11)

$$\omega = \omega_r + i\gamma$$

$$\omega_r = \frac{k c_s}{[1 + k^2 c_s^2 / \omega_{pe}^2]^{1/2}}$$

$$\gamma = \sqrt{\pi} \frac{\omega^3}{2 k^2 c_s^2} \rightsquigarrow \frac{v_0 - \omega/k}{v_{th}}$$

$$\sim \omega \frac{v_0 - \omega/k}{v_{th}} \sim \omega \frac{v_0 - c_s}{v_{th}}$$

You will get here the dispersant relation will be have omega is equal to omega real plus i gamma, omega real is the same as you obtain from the fluid theory, the real frequency of a sound wave, which is k c s upon 1 plus k square c s square upon omega p i square under root and the growth rate gamma turns out to be equal to root pi omega cube upon 2 k square c square into omega minus, **sorry** this is v 0 minus omega by k upon thermal velocity of electrons.

As I mentioned omega by k is like c s, v 0 has to be slightly more than c s. So, this quantity is quietly small but significant. So, whenever omega is of the order k c s growth rate is comparable to omega into this ratio v 0 minus omega by k upon v thermal or this like c s, this is maybe I

would say one-fiftieth but still it quite significant. So, this is let me write this as ω into v_0 minus sound velocity upon thermal velocity of electrons. So, this is still significant. So, sound waves have been found to be generated in plasmas carrying currents, even simple discharges will produce plasma waves, sound waves.

Sound waves are like acoustical phonons and solids. In a solid, whenever the sound waves travel, we say that acoustical phonons exist. So, whenever you apply a d c electric field to a conductor, the electrons in the drift they suffer collisions with phonons and that gives rise to resistivity. Similarly, in plasmas, if you pass a current in a plasma and sound waves are generated, then these waves can also give rise to plasma resistivity, which could be significantly higher than the resistivity due to particle collisions, electron ion collisions or electron neutral collisions. And I think in our next lecture, we shall talk about the effect of such instabilities on resistivity. I think, I would like to stop at this stage. Thank you.
