The One Dimensional Potential Well and Particle in a Box

In my previous lecture, near the end of the previous lecture, we had started with the solution of the particle, in a one-dimensional potential. Well, we will continue with that, and we hope today we will be able to start the solution corresponding to a particle, in a three dimensional box, which has many important applications.

(Refer Slide Time: 01:01)

Potential Well Problem

Diagram of a potential well with depth V_0 and width a . The well is divided into two regions: I (left) and II (right). The potential is 0 for $x < -a/2$ and $x > a/2$, and V_0 for $-a/2 < x < a/2$.

Wave functions:

$$\psi_I(x) = A \cos kx$$

$$\psi_{II}(x) = C e^{-\kappa x}$$

Boundary conditions at $x = a/2$:

$$A \cos \frac{ka}{2} = C e^{-\kappa a/2}$$

$$-k A \sin \frac{ka}{2} = -\kappa C e^{-\kappa a/2}$$

Dividing the two equations:

$$\frac{\frac{ka}{2} \tan \frac{ka}{2}}{\frac{ka}{2}} = \frac{\kappa a/2}{\frac{ka}{2}}$$

$$\xi \tan \xi = \eta$$

Energy levels:

$$\xi^2 = \frac{k^2 a^2}{4} = \frac{2\mu E a^2}{4\hbar^2}$$

$$\eta^2 = \frac{\kappa^2 a^2}{4} = \frac{2\mu (V_0 - E) a^2}{4\hbar^2}$$

$$\xi^2 + \eta^2 = \frac{2\mu V_0 a^2}{4\hbar^2} = \omega^2$$

NPTEL logo is visible in the bottom left corner of the slide.

So, let us start with the one dimensional potential well problem, in which the potential is 0, between x less than a by 2 and lying between minus a by 2 and plus a by 2 and V_0 outside. So, the particle is confined, in this well. And, we had solved the Schrödinger equation; this is the origin, since V of minus x is equal to V of x the potential is symmetric. So, the wave functions, are either symmetric or anti symmetric.

First, we considered the symmetric wave function and we solved it and we found that the solution of the Schrödinger equation in region one, was equal to $a \cos kx$ and the solution in the second region was equal to $c e^{-\kappa x}$. So, you have here, an exponentially decaying solution in the second region. We then match the wave function at $x = a/2$ and its derivative. So, we got two equations, $a \cos ka/2$ is equal to $c e^{-\kappa a/2}$, this is the continuity of wave function at $x = a/2$.

And the continuity of the derivative, will be the differential $-\sin ka/2$ is equal to $-\kappa c e^{-\kappa a/2}$. And, if I divide for non-trivial solution as we discussed last time, one with respect to the other.

We will have $ka/2 \tan ka/2$ is equal to $\kappa a/2$. We write this quantity as ξ . So, $\xi \tan \xi$ is equal to η , where η is equal to $\kappa a/2$. So, we know that ξ^2 is equal to $k^2 a^2/4$ or this is equal to $2\mu e a^2/4\hbar^2$ and η^2 is equal to $\kappa^2 a^2/4$. So, κ^2 is equal to $2\mu V_0 - e a^2/4\hbar^2$ and $\xi^2 + \eta^2$ is equal to $2\mu V_0 a^2/4\hbar^2$, which is a constant. So, this I put as α^2 .

So, then η^2 is equal to $\alpha^2 - \xi^2$. And, therefore, η will be equal to $\alpha^2 - \xi^2$. So, you see for a given value of μ , for a given value of a and of course, \hbar is a constant, the only unknown parameter is ξ and therefore, ξ . For a given potential well, α is known, μ is known, V_0 is known, a is known, \hbar is a constant. So, α is a number, may be, we will discuss a very simple example little later.

(Refer Slide Time: 05:37)

Therefore, the transcendental equation is, $\xi \tan \xi$ for symmetric states is equal to $\alpha^2 - \xi^2$, we said both of them equal to η . So, what we do is that, we plot the left hand side and the right hand side, as a function of ξ . Now, what is the right hand side? So, as we have seen that if I square this, I get $\alpha^2 - \xi^2$ is equal to η^2 . So, $\xi^2 + \eta^2 = \alpha^2$. So, in the ξ η plane, $x^2 + y^2 = \alpha^2$ is the equation of a circle of radius α .

Now, the left hand side as you know that, $\tan \xi$ is equal to 0, for ξ is equal to 0, 2π and 4π and $\tan \xi$ is equal to plus or minus infinity at $\pi/2$, $3\pi/2$ and so on. So, let me plot this carefully. So, I have here the horizontal axis is ξ . So, as ξ equal to 0, it is zero and it will go to infinity, at $\pi/2$ and then there is a discontinuity like this. And, then it will become infinity like this, because $\tan \xi$ has an infinite discontinuity at $\pi/2$ and it will become zero at π , then it will become infinity at $3\pi/2$ and so on.

So, this is the plot of $\xi \tan \xi$, as a function of ξ , it will have infinities at $\pi/2$, $3\pi/2$ and so on. And, if you have zeroes at 0, 2π and 4π , now this is the left hand side, let me now plot the right hand side. Right hand side is the η axis. So, $\eta^2 = \alpha^2 - \xi^2$. So, this is quadrant of a circle. So, I will ask you, to tell me the value of α , if α is 2, then I will draw a

quadrant of a circle, this is pi by 2 that is 1.5. So, 2 is somewhere here and if alpha is 2 I will have a circle of radius 2. Then at this point, the left hand side and right hand side are equal. And, the value of xi, that is suppose something like 1.4 or something, that is a Eigen state of the problem.

So, what is alpha? Alpha is under root of $2 \mu V_0 a^2$ by $4 \hbar^2$ cross square, if suppose, alpha is four, then I have to draw a circle of radius four unit. So, pi is here, $3\pi/2$ is here, 4 will be somewhere here. So, I will draw a quadrant of a circle, of radius 4 and then there will be two places where the left hand side will intersect, the right hand side. And, there will be then two symmetric states, we have considered till now only the symmetric states.

We will consider the anti symmetric stages in a moment. So, these are the discreet Eigen values of the problem and whenever you have an equation like this, you say it is a transcendental equation; it is satisfied only, when the left hand side is equal to the right hand side. And that will happen only for certain discrete values of xi. If, xi was equal to eight, then you have to draw a circle of radius eight, if alpha is eight, then you'll have three symmetric notes.

(Refer Slide Time: 11:16)

Handwritten notes on a blue grid background showing the derivation of the transcendental equation for antisymmetric states in a potential well.

Diagram of a potential well (I) with width a and depth V_0 . The region is divided into two parts: $|x| < a/2$ and $|x| > a/2$.

Antisymmetric Solution

For $|x| < a/2$, the wave function is $\psi(x) = A \sin kx$.

For $|x| > a/2$, the wave function is $\psi(x) = C e^{-\kappa x}$.

The Schrödinger equation for the well is $\frac{d^2\psi}{dx^2} + k^2\psi(x) = 0$.

The Schrödinger equation for the barrier is $\frac{d^2\psi}{dx^2} - \kappa^2\psi(x) = 0$.

The relationship between k and κ is $k^2 = \frac{2\mu}{\hbar^2}(V_0 - E)$.

The boundary conditions at $x = a/2$ are:

$$A \sin \frac{ka}{2} = C e^{-\kappa a/2}$$

$$k A \cos \frac{ka}{2} = -\kappa C e^{-\kappa a/2}$$

Dividing the two equations gives the transcendental equation:

$$\frac{ka}{2} \cot \frac{ka}{2} = -\frac{\kappa a}{2}$$

Letting $\xi = \frac{ka}{2}$ and $\eta = \frac{\kappa a}{2}$, the equation becomes:

$$-\xi \cot \xi = \eta = \sqrt{\alpha^2 - \xi^2}$$

Let me skip here, for a moment, we will come back to this figure a little later. Now, consider the anti symmetric stage. So, we will go back to the potential well, that we had

discussed earlier, that I have here this, as the potential well, till now we have considered, the symmetric states, in which the solution is $\cos k s$ in this region.

So, region one is x less than $a/2$, the Schrödinger equation is $d^2 \psi / dx^2 + k^2 \psi = 0$. So, solution can be either, $\cos k x$ or $\sin k x$. So, now we consider the anti symmetric solution. In the anti symmetric solution, we will have in the region x less than $a/2$, we will have ψ of x is equal to $\sin k x$ and for x greater than $a/2$, we will have again the same solution.

The Schrödinger equation will be $d^2 \psi / dx^2 - \kappa^2 \psi = 0$. So, the solutions will be ψ of x will be an exponentially decaying solution, $e^{-\kappa x}$. once again, we apply the continuity conditions. The continuity of the wave function will be, $\sin k a/2$, will be equal to $c e^{-\kappa a/2}$ and ψ of x should be continuous.

And then, I have the derivative continuous, that is, $k \cos k a/2$ is equal to $-\kappa c e^{-\kappa a/2}$. So, I again divide this equation and a cancels out. So, non-trivial solution, I multiply $k a/2 \cot k a/2$ is now equal to $-\kappa a/2$. The value of κ is still the same, which is equal to $\sqrt{2m(V_0 - E)}$. So, once again, I will have the similar kind of thing. So, I take the minus sign here. So, I get $-\cot \xi$ is equal to η , that is η and that we have shown to be, equal to the under root of α^2 , minus ξ^2 .

(Refer Slide Time: 14:41)

So, the right hand side remains the same. So, we summarize the result. So, for the symmetric solution we had $\xi \tan \xi$ is equal to $\sqrt{\alpha^2 - \xi^2}$ and $-\xi \cot \xi$ is equal to $\sqrt{\alpha^2 - \xi^2}$.

So, this is equal to η , and this is equal to this corresponds to symmetric states and this corresponds to anti symmetric states. Now, let me plot it again. So, we will have something like this, suppose this is $\pi/2$, this is π , this is $3\pi/2$ and so on. So, $\xi \tan \xi$ goes to infinity here, So, you have $\pi/2$, $3\pi/2$ and $5\pi/2$ and this will go to infinity, what I have plotted, is $\xi \tan \xi$, as a function of ξ . So, this is η , now let me plot minus in red pen. So, $\cot \xi$ times, $\cot \xi$ tends to a finite number at ξ equal to 0, because $\cot \xi$ tends to infinity, ξ tends to 0 so, the product is, $\pi/2 \cot \xi$ is 0.

So, it will go to infinity at π and then it will go like this, at $5\pi/2$ it will go to infinity. So, the quantity which I've shown, with red pen is $\xi \cot \xi$. And, there will be again at $5\pi/2$ this, at this point will be infinity. In the right hand side, is a quadrant of a circle, whose radius is α . So, let me say α is equal to 2. The quantity 2 is less than π . So, the quadrant of the circle would be something like this is $\pi/2$. So, you can see that, there'll be one symmetric and one anti symmetric state.

If α was equal to 1, then this will be only one symmetric state, only one discrete state. If α was 4, then this is the radius which is greater than π , then there will be two symmetric states and one anti symmetric state. And suppose α is 6, then you'll have to draw a radius of 6 then, it will be two symmetric states and two anti symmetric states. As, the value of α becomes larger and larger, that is as the value of the 0 becomes larger and larger, we will have larger and larger number of discrete states, that are possible.

In general, a potential well has a finite number of states; it has a finite number of discrete states. And, how to determine the number, when you given the value of μ , given the value of V_0 , given the value of a and I know \hbar cross, I will first calculate the value of α . If the value of α is less than $\pi/2$, I know that there is one symmetric state. If α lies between $\pi/2$ and π then, one symmetric and one anti symmetric. If α lies between π and $3\pi/2$ then two symmetric and one anti symmetric and so on.

(Refer Slide Time: 20:28)

$\mu = m_p = 1.67 \times 10^{-27} \text{ kg}$
 $V_0 \approx 25 \text{ MeV} \approx 4 \times 10^{-12} \text{ J}$
 $a \approx 3.65 \times 10^{-15} \text{ m} = 3.65 \text{ F}$
 $\hbar \approx 10^{-34} \text{ Js}$
 $\alpha = \sqrt{\frac{2\mu V_0 a^2}{4\hbar^2}} \approx 2.0$
 $\xi = 1.02987 \Rightarrow E = 6.63 \text{ MeV}$
 $\xi = 1.89549 \Rightarrow E = 22.45 \text{ MeV}$
 $E < 0$
 $0 < E < V_0 \Rightarrow \text{finite \# of discrete states}$

The diagram shows a potential well of depth 25 MeV. Two discrete energy levels are indicated: one at approximately 6.63 MeV and another at approximately 22.45 MeV. The wavefunctions for these states are shown as symmetric and antisymmetric curves within the well.

So, let me consider a simple case, a proton in a potential. So, I assume that the mass of the particle, is the proton mass and the proton mass is about 1.67 into 10 to the power of minus 27 k g. suppose, this approximately represent the deuteron problem 25 M e V. So, this is about 4 into 10 to the power minus 12 joules, 25 M e V and a the range of the potential is equal to 3.65 into 10 to the power of minus 15 meters is known as a Fermi, in honor of the famous nuclear physicist, Enrico Fermi, 3.65 Fermi. One Fermi is 10 to the power minus 15 meter.

And you know the value of h cross, which is about 10 to the power of minus 34 joule. It is always better to use, consistently the m k system of unit, and then there is no chance of an error. So, if you substitute, this is equal to $2\mu V_0 a^2$ by $4\hbar^2$ square, you substitute for μ , 1.67 V_0 is 10 to the power minus 7 joules, a is 3.65 into 10 to the power minus 15 \hbar cross is 10 to the power minus 34, if you substitute that and take the under root you will get α is equal to 2.0.

So, if α is 2.0. So, then α lies between $\pi/2$ and π . And, therefore there will be two symmetric states. So, there are two states, one symmetric and one anti symmetric, the corresponding values of ξ , for which the left hand side is equal to the right hand side, this is equal to 1.02987 it can be obtained very easily. And the corresponding value of e comes out to be 6.63 M e V and the other value is 1.89549, the corresponding value

of e is 22.45 MeV. Suppose, if α is equal to 2. So, this is the first value of ξ and this is the second value of ξ , these are the discrete energy Eigen values of the problem.

So, therefore we obtained two states and for this particular problem, the potential well and the ground state, that is the depth is about 25 MeV and here is the first state which has 6.63. And, the wave function will be a symmetric wave function like this.

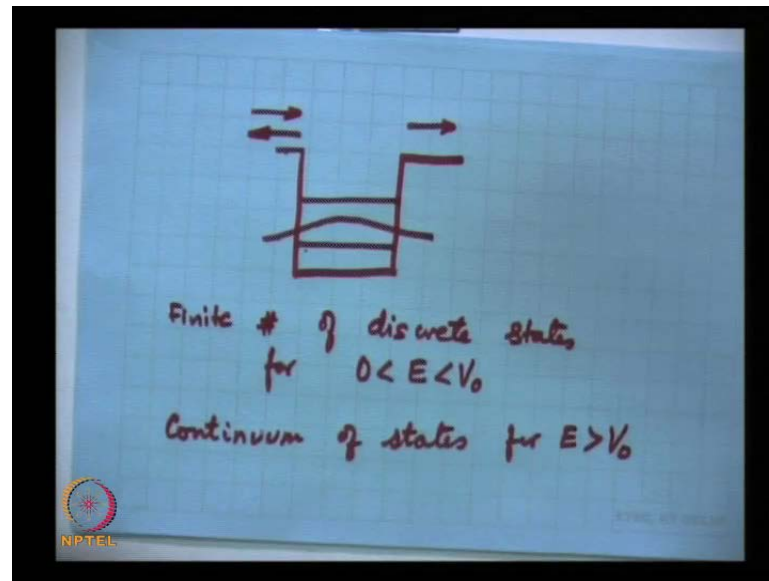

It should be cosine solution here and exponentially decaying solution here. And the second one which is right at top has a value of about 22.45 MeV and it will be an antisymmetric solution.

So, it will be zero here and something like this. This is the symmetric solution cosine inside and outside it is exponential this is an antisymmetric solution. We showed that in the harmonic oscillator problem, there were alternately symmetric and antisymmetric. First, the ground state is symmetric then antisymmetric then symmetric then antisymmetric and so on. This same is true in all cases that you'll have first the symmetric state then antisymmetric and in this particular case there are only two discrete states.

There are, only finite number of discrete states if it were instead of two twenty five MeV if it were 200 and 50 MeV then there would have been a much larger number of states so, finite number of discrete states. I would like to conclude this discussion by mentioning that we have considered only zero less than e less than V_0 .

And we have obtained we have shown that we will have a finite number of discrete states. E can never be less than zero, because no condition can be satisfied e can never be less than 0 then the minimum value of the potential energy e can of course, be greater than 0 e can of course, be greater than 0 then once again you'll have a particle which comes in from the left and will get reflected and will get transmitted.

(Refer Slide Time: 26:25)

So, therefore, in this particular case what I told you at the end is important, that you have two states two types of solution one discrete bound state in which the wave function is exponentially decaying at large distance and then you have incident wave and the reflective wave. So, you have a finite number of discrete states discrete states for E lying between 0 and V_0 .

And the continuum of state that is all possible values of E for E greater than V_0 . These are also known as scattering states. In all problems of quantum mechanics for a given potential energy distribution you have two types of solutions one is the discrete bound state solution and the other is the continuum of scattering state solution.

And the simplest example that I could think of is the simplest atom hydrogen atom. We will discuss that in greater detail later, but the hydrogen atom you know it consists of a proton and an electron and there are two types of solutions.

One in which the electron and the proton are together to form a bound state and you have discrete energy level of the atom. These are, the discrete bound state of the Schrödinger equation and the second is let us suppose, proton is here and the electron is coming from the last distance.

(Refer Slide Time: 28:32)

Proton is coming here and the electron is coming and getting scattered. Here, it is a continuum of energy value all possible values of energy are allowed. And these are the scattering states. So, in the hydrogen atom problem in the hydrogen atom problem you will have the potential energy function is given by minus $z e^2$ by r and if you plot this $z e^2$ by r minus $z e^2$ by r then you'll have a set of discrete state in fact, infinite number of discrete states.

These lead to the hydrogen atom spectrum and for e greater than zero you'll have a continuum of states in which a particle will come from last distance interact with the proton and gets scattered that hopefully we will discuss at a later time.

(Refer Slide Time: 29:37)

So, till now we have considered four five problems. First we consider the free particle problem in which the potential energy is zero everywhere. We found only plane wave solution continuum of wave function and we found this was $i p x$ by \hbar cross these are the wave functions ψ_p of x . All values of energy are allowed you normalizes by putting one over root two pi \hbar cross then you, consider a particle in an infinitely deep potential box that, this is infinite then you have only discrete states no continuum of states.

Only, discrete states and we had ψ_n of x , which is equal to the normalization constant sine n of x by l and you have a this from 0 less than x less than l then. We consider the harmonic oscillator problem in which there is V of x is half μ .

This also has an infinite number of discrete states. The wave functions are as I have told you many times these are the hermit gauss functions. Finally, we consider that potential well problem and in which there are two classes of solutions. One discrete bound states finite number of discrete bound states and for e greater than zero you have a continuum of states. These are the scattering states and when we consider this problem then there are no bound states only all values of E greater than 0 are allowed. These are a continuum of scattering states.

So, if you solve the Schrödinger equation for a given potential distribution. We have considered consistently only one dimensional potential problem. Then, you will get two types of solutions. One in which the particles are confined at the origin, those are the

discrete bound states for the problem and the energy levels are discrete and then you have in addition a continuum of scattering states which may or may not exist.

For example in the case of the harmonic oscillator problem or in the case of a particle in an infinitely deep potential well problem there are no scattering states. So, this almost completes this analysis of one dimensional problem. Today, I want to continue the discussion and consider a very simple and very important problem of particle in a box and it very accurately represents the free electrons in a metal.

(Refer Slide Time: 32:48)

So, we do the particle in a three-dimensional box in a three dimensional box. And of course, we have to solve the three dimensional Schrödinger equation. This is the probably simplest and a very important solution of the Schrödinger equation.

So, the three-dimensional Schrödinger equation is given by del square of psi plus two mu by h cross square E minus v psi of x y z is equal to 0. Now I consider an electron or a proton which is confined inside a box, whose side is l that is what I mean by confined it is an infinitely deep. But it is a three-dimensional box the particle cannot go out of the box and therefore, the wave function has to vanish, at all point of the surface of the box. So, for example, if I take this as my x axis so, this plane is x equal to 0 and this plane this side is x equal to l and similarly, if the vertical axis is the z axis then the base is z equal to 0 and the top one the top roof is z equal to l.

And of course, for a problem like this, one has to use Cartesian system of co ordinates and therefore, the del square psi operator becomes delta two psi by delta x's square plus delta 2 psi by delta y square, plus delta 2 psi by delta z square. And inside the box the potential is zero. So, therefore, V is 0. So, you get 2 mu e by h cross square psi. So, that I represent by k square psi is equal to 0. Where, k square let me write it down by red. K square is defined to be equal to once again two mu e by h cross's square I want to solve this problem. So, once again I have a box of length I have a metal for example, I have a metal cube each side is of length l.

There is an electron free inside the metal, but the potential is so, deep that it cannot escape from the metal. So, the wave function associated with the electron must vanish on the surface of the metal. So, let me solve this equation and apply the boundary condition that on all six faces the wave function is zero. So, we use the method of separation of variables. So, this is the method of separation of variables.

And we write this as psi of x y z as equal to x of x of y of y and z of z let me try the sum this is the method which sometimes it works sometimes it does not work, but in this case we know that it will work therefore, we are using that. So, what is delta two psi by delta x square. So, this will be delta two psi by delta x square will be equal to this and this will be constant. So, y and z can be and then become the differential d 2 x by d x square.

(Refer Slide Time: 37:51)

$$YZ \frac{d^2X}{dx^2} + XZ \frac{d^2Y}{dy^2} + XY \frac{d^2Z}{dz^2} + k^2 XYZ = 0$$

$$\div XYZ$$

$$\frac{1}{X} \frac{d^2X}{dx^2} + \frac{1}{Y} \frac{d^2Y}{dy^2} + \frac{1}{Z} \frac{d^2Z}{dz^2} = -k^2$$

$$\underbrace{\frac{1}{X} \frac{d^2X}{dx^2}}_{=-k_x^2} + \underbrace{\frac{1}{Y} \frac{d^2Y}{dy^2}}_{=-k_y^2} + \underbrace{\frac{1}{Z} \frac{d^2Z}{dz^2}}_{=-k_z^2} = -k^2$$

$$k^2 = k_x^2 + k_y^2 + k_z^2$$

$$\frac{1}{X} \frac{d^2X}{dx^2} = -k_x^2 \Rightarrow \boxed{\frac{d^2X}{dx^2} + k_x^2 X(x) = 0}$$

And similarly, $\Delta^2 \psi$ by Δy^2 and $\Delta^2 \psi$ by Δz^2 ; so, if I substitute the solution with this equation; then what I will get is the following $\Delta^2 \psi$ times z into $\Delta^2 x$ by Δx^2 remember that we have assumed that let me do this again let me do this again. We have assumed that ψ of x is equal to $x y x y$ and z . So, we substitute it in this equation. So, we get $y z \Delta^2 x$ by Δx^2 then $x y \Delta^2 x z \Delta^2 y$ by Δy^2 plus x . The third term will be $x y \Delta^2 z$ by Δz^2 plus k^2 into ψ is $x y z$. X as a function of x y as a function of y and z as a function of z . So, I substituted this solution in this equation and I obtain this. The next is very simple that, I divide the whole equation by ψ that is I divide by $x y z$. So, I get one over capital $x \Delta^2 x$ it is a very straight forward $\Delta^2 x$ by Δx^2 plus one over $y \Delta^2 y$ by Δy^2 plus 1 over $z \Delta^2 z$ by Δz^2 plus k^2 and k^2 . So, this I write as minus k^2 now this is a function of x this term is a function of y and this term is a function of z .

How can a function of x and plus a function of y and plus a function of z be equal to a constant. You know $x y z$ are independent variables it could only happen if each term is a constant. So, I this must be equal to, let us suppose minus $k x^2$. You cannot set it equal to your positive constant, because then as we will show later it will not be able to satisfy the boundary conditions. This will be equal to minus $k y^2$ and this will be equal to minus $k z^2$.

Then you will have k^2 is equal to $k x^2$ plus $k y^2$ plus $k z^2$ $k x k y k z$ are just are numbers symbols. So, one over $x \Delta^2 x$ by Δx^2 I have said this equal to your minus of $\cos v$, as I have said this equal to $k x^2$. So, therefore, if I multiply this out this will become $\Delta^2 x$ by Δx^2 plus $k x^2$ multiplied by x of x is equal to 0 now obvious equation this is a simple second order equation and I know the solution.

(Refer Slide Time: 42:16)

$$X(x) = A \sin k_x x + B \cos k_x x$$

$$x=0 \quad \& \quad x=L$$

$$0 = 0 + B \Rightarrow B=0$$

$$0 = A \sin k_x L$$

$$\sin k_x L = 0 \Rightarrow k_x L = n_x \pi \quad n_x = 1, 2, \dots$$

$$k_x = \frac{n_x \pi}{L} \quad ; \quad n_x = 1, 2, 3, \dots$$

$$k_y = \frac{n_y \pi}{L} \quad ; \quad n_y = 1, 2, 3, \dots$$

And the solutions are the solutions are x of x is equal to $a \sin k_x x$ plus $b \cos k_x x$. Now if this is the x axis then the wave function has to vanish on all points on the plane x equal to zero and on all points on the plane x is equal to L . So, the wave function has to vanish. So, if I put x is equal to 0, the wave function has to be 0. So, 0 must be equal to this is 0 plus b at x equal to 0. So, therefore, this will give me b equal to 0. So, this term goes out b equal to 0.

Then, we have at x is equal to L would the function must be 0. So, 0 is equal to $a \sin k_x L$ as we had done quite sometimes earlier there are now two possibilities one is that either a is 0 or $\sin k_x L$ is 0. If a is zero, then the wave function is zero at all places. So, ψ is equal to 0 everywhere. That is known as the trivial solution. So, a cannot be zero so, we can have only $\sin k_x L$ must be 0 and. So, therefore, which will imply $k_x L$ is equal to $n_x \pi$, where n_x will be not zero because again if it is zero then k_x is zero if k_x is zero then the wave function is zero everywhere. So, that is again a trivial solution. So, you have the allowed values of k_x are $n_x \pi$ by L where n_x is equal to one two three four.

Similarly, we have solved this equation because the y equation is one over y d 2 y by y square is equal to minus k_y square. So, that will lead to the will lead to the equation $d^2 y$ by y square plus k_y square y of y is equal to 0. Once again, we will have sine and cosine and exactly the same thing. So, we will find that they allow values of k_y will be $n_y \pi$ by L .

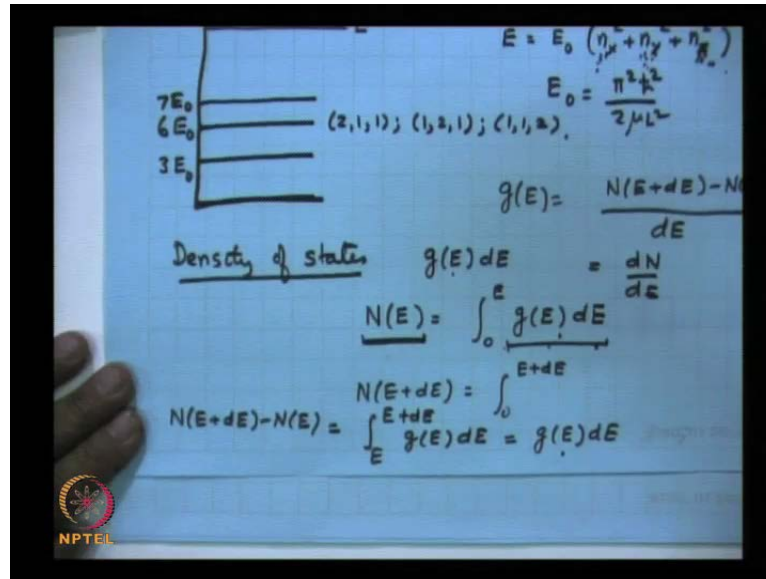

y π by l that n_y also takes the same set of values one two three etcetera and finally, the z component the k_z will be $n_z \pi$ by l and n_z takes also this thing.

(Refer Slide Time: 46:10)

$$\begin{aligned}
 k_x^2 + k_y^2 + k_z^2 &= k^2 = \frac{2\mu E}{\hbar^2} \\
 \left(\frac{n_x \pi}{L}\right)^2 + \left(\frac{n_y \pi}{L}\right)^2 + \left(\frac{n_z \pi}{L}\right)^2 &= \frac{2\mu E}{\hbar^2} \\
 \frac{2\mu E}{\hbar^2} &= (n_x^2 + n_y^2 + n_z^2) \frac{\pi^2}{L^2} \\
 E &= \frac{\pi^2 \hbar^2}{2\mu L^2} (n_x^2 + n_y^2 + n_z^2); \quad n_x, n_y, n_z = 1, 2, 3, \dots \\
 \Psi &= \left(\sqrt{\frac{2}{L}}\right)^3 \sin \frac{n_x \pi}{L} x \sin \frac{n_y \pi}{L} y \sin \frac{n_z \pi}{L} z \\
 &\quad 0 < x, y, z < L
 \end{aligned}$$

So, you will have if you recollect that therefore, we had k_x^2 plus k_y^2 plus k_z^2 was equal to k^2 this is equal to $2\mu E$ by \hbar^2 now we find that k_x takes discrete values. So, we have $n_x \pi$ by l whole square, plus $n_y \pi$ by l whole square plus $n_z \pi$ by l whole square. This is equal to $2\mu E$ by \hbar^2 cross square. So, I bring it to the left hand side. So, we have $2\mu E$ by \hbar^2 cross square is equal to is equal to n_x^2 plus n_y^2 plus n_z^2 times π^2 by l^2 . We get the remarkable result that the energy levels are discrete and you will have $\pi^2 \hbar^2$ cross square by $2\mu l^2$ n_x^2 plus n_y^2 plus n_z^2 , where n_x , n_y and n_z they can, each take the value one two three. So, these are the discrete values of the energy and corresponding to each set of n_x , n_y , n_z . We have a wave function and that is that is k_x was equal to if you remember k_x is $n_x \pi$ by l . So, the wave function will be some normalization constant which I can show to you equal to $\sqrt{2/L}$ cubed \sin of $n_x \pi$ by l into x \sin of $n_y \pi$ by l into y \sin of $n_z \pi$ by l into z this is $0 < x, y, z < l$ inside the box.

(Refer Slide Time: 49:36)

So, these are the normalized wave functions and these are the discrete states. So, what is the ground state value the ground state value is n_x is equal to one n_y is equal to 1 n_z is equal to 1. So, three $\pi^2 \hbar^2$ cross square by $2\mu L^2$ square. So, you have here if you if you plot this E then the ground state is something like say three E_0 where you see the allowed value of E is say $E_0 n_x^2 + n_y^2 + n_z^2$ E_0 is equal to $\pi^2 \hbar^2$ cross square by $2\mu L^2$ square. So, if n_x is 1 n_y is one n_z that is the ground state. So, this is 1 plus 1 plus 1 that is 3. Then you will have 2 1 1 2 1 1 2 that state will be three fold degenerate state and this will be four plus one plus one that is $6E_0$.

So, this will be 2 1 1 2 1 and 1 1 2 and then you can have 3 1 1 that is $7E_0$ 3 1 1 3 1 and 1 1 3 so, that is $7E_0$ and so on. You can write down the various states very quickly there will be for a given value of E there will be many sets of integers whose sum of square is a given number. So, I have been able to obtain, the exact solution for a particle in the three dimensional box for a electron confined in a cube volume L^3 and have been able to obtain the exact wave functions and the exact energy levels and there are infinite number of states.

What I would like to calculate and what is of extreme importance in solid state physics in astrophysics and in many areas is to calculate the density of states that is, density of state meaning when the energy level becomes very large states have very closely spaced and there are very large number of states.

And $g(E) dE$ represents the number of states, whose energy lies between E and $E + dE$. Once again $g(E) dE$ represents the number of states whose energy lies between E and $E + dE$. So, let us suppose I want to find out the total number of states. Which had energy less than E then $N(E)$ will be equal to $\int_0^E g(E') dE'$.

This is the density of states and this is the total number of states. Whose energy is less than E that is a difference in dimension between $N(E)$ and $g(E)$ has to be a little careful $g(E)$ represents the density of states. So, that $g(E) dE$ represents the number of states, whose energy lies between E and $E + dE$ and $N(E)$ will represent the total number of states whose energy is less than E . Now that the quantity and if I am able to find out $N(E)$ then of course, I can differentiate $N(E)$ to obtain $g(E)$ because $N(E)$ is given by base. $N(E + dE)$ I can write this down as $\int_0^{E+dE} g(E') dE'$ and if I subtract one from the other. So, $N(E + dE) - N(E)$ is then equal to $\int_E^{E+dE} g(E') dE'$. So, in this small interval this becomes equal to $g(E) dE$.

And so therefore, $g(E)$ is equal to $\frac{N(E + dE) - N(E)}{dE}$ so, $g(E)$ will become $\frac{dN(E)}{dE}$ so, dE is extremely small than dN by dE . So, if I am able to find out $N(E)$ then a simple differential will give me $g(E)$. So, in next lecture, what I will do is that I will obtain an expression for $N(E)$ and obtain the density of states and thereby we will be able to obtain the property of the electron inside a metal. A similar kind of analysis can be applied, even for the electrons inside a white dwarf star. So, we will probably discuss that very briefly **thank you**.
