The Angular Momentum - I
Lecture No. # 01
The Angular Momentum Problem

In my last lecture, near the end of that lecture, we had started the Angular Momentum Problem in Quantum Mechanics. And we had, we will continue our discussion on that, I discussed the Eigen values and corresponding Eigen functions for the angular momentum.

(Refer Slide Time: 00:55)

The image shows handwritten mathematical derivations on a grid background. At the top left, it states $\vec{L} = \vec{r} \times \vec{p}$. To the right, a determinant is written for the cross product: $\begin{vmatrix} \hat{x} & \hat{y} & \hat{z} \\ x & y & z \\ p_x & p_y & p_z \end{vmatrix}$. Below this, the expression $L_z = x p_y - y p_x$ is written. Then, the operator form is given: $L_z \psi = -i\hbar \left[x \frac{\partial \psi}{\partial y} - y \frac{\partial \psi}{\partial x} \right]$ with r, θ, ϕ noted. The next two lines show the conversion to spherical coordinates: $x \frac{\partial \psi}{\partial y} = r \sin \theta \cos \phi \left[\frac{\partial \psi}{\partial r} \frac{\partial r}{\partial y} + \frac{\partial \psi}{\partial \theta} \frac{\partial \theta}{\partial y} + \frac{\partial \psi}{\partial \phi} \frac{\partial \phi}{\partial y} \right]$ and $y \frac{\partial \psi}{\partial x} = r \sin \theta \sin \phi \left[\frac{\partial \psi}{\partial r} \frac{\partial r}{\partial x} + \frac{\partial \psi}{\partial \theta} \frac{\partial \theta}{\partial x} + \frac{\partial \psi}{\partial \phi} \frac{\partial \phi}{\partial x} \right]$. The NPTEL logo is visible in the bottom left corner of the slide.

We had said that, we represented as in classical mechanics by the \vec{r} cross \vec{p} but, now \vec{p} is a differential operator, so for example, L_z will be equal to $y p_x$ minus $x p_y$, so the cross product is x cap y cap and z cap and $x y z p_x p_y p_z$. So, $p_x p_y$ so I'm sorry, so this will be L_z will be L_z will be $x p_y$ minus $y p_x$ and similarly, L_x similarly, L_y . So, this if I write the differential represent operator representation. So, this becomes minus $i \hbar$

cross x delta, so L_z operating on a wave function ψ will be $\delta \psi$ by δy minus $\delta \psi$ by δx .

Now, I want to express this in terms of the spherical polar coordinates r θ ϕ , so that we know what is x that is $r \sin \theta \cos \phi$, so the first term, so $x \delta \psi$ by δy will be equal to $r \sin \theta \cos \phi$ multiplied by. Now I want to express this in terms of spherical polar coordinates.

So, it will be $\delta \psi$ by δr time's δr by δy plus $\delta \psi$ by $\delta \theta$ into $\delta \theta$ by δy plus $\delta \psi$ by $\delta \phi$ into $\delta \phi$ by δy , this is the first term. And the second term will be $y \delta \psi$ by δx and this will be $r \sin \theta \sin \phi$ and $\delta \psi$ by δx will be $\delta \psi$ by δr y here will be replaced by $x \delta r$ by δx plus $\delta \psi$ by $\delta \theta$ $\delta \theta$ by δx plus $\delta \psi$ by $\delta \phi$ although it looks very combustion but, the analysis is quite straight forward.

So, as you can see we require therefore, δr by δy , $\delta \theta$ by δy , $\delta \phi$ by δy , $\delta \theta$ by δx , $\delta \phi$ by δx and δr by δx . So these are the expressions that, we would like to express in terms of the spherical polar coordinates.

(Refer Slide Time: 04:44)

Handwritten mathematical derivations for spherical coordinates:

$$\begin{aligned}
 r \sin \theta \cos \phi &= x \\
 r \sin \theta \sin \phi &= y \\
 r \cos \theta &= z \\
 \frac{x^2 + y^2}{z^2} &= \frac{r^2 \sin^2 \theta}{r^2 \cos^2 \theta} \\
 r^2 &= x^2 + y^2 + z^2 \Rightarrow 2r \frac{\partial r}{\partial x} = 2x \Rightarrow \frac{\partial r}{\partial x} = \sin \theta \cos \phi \\
 2r \frac{\partial r}{\partial y} &= 2y \Rightarrow \frac{\partial r}{\partial y} = \sin \theta \sin \phi \\
 \tan \phi &= \frac{y}{x} \Rightarrow \sec^2 \phi \frac{\partial \phi}{\partial x} = -\frac{y}{x^2} = -\frac{r \sin \theta \sin \phi}{r^2 \sin^2 \theta \cos^2 \phi} \\
 \frac{\partial \phi}{\partial x} &= -\frac{1}{r} \frac{\sin \phi}{\sin \theta} \\
 \sec^2 \phi \frac{\partial \phi}{\partial y} &= \frac{1}{r \sin \theta \cos \phi} = \frac{1}{r} \frac{\cos \phi}{\sin \theta}
 \end{aligned}$$

NPTEL

So, as we had said that, the spherical polar coordinates were defined as $r \sin \theta \cos \phi$ was equal to x , $r \sin \theta \sin \phi$ was equal to y and $r \cos \theta$ was equal to z . So,

if we square and add then it will become sine square theta cos square phi sine square theta sine square phi, so if we add them it become sine square theta plus cos square theta.

So, r^2 is equal to $x^2 + y^2 + z^2$, so if I differentiate with respect to x , so it becomes $2r \frac{dr}{dx}$ is equal to $2x$ therefore, we will have $\frac{dr}{dx}$ will be equal to $\frac{x}{r}$ but, x is equal to $r \sin \theta \cos \phi$; so this will be $\sin \theta \cos \phi$. Similarly, $2r \frac{dr}{dy}$ now, when I write this partial differentiation, when I differentiate partially with respect to y , then x and z have to be kept constant. So, this will be equal to $2y$, so this will imply that $\frac{dr}{dy}$ is equal to $\frac{y}{r}$ that is $\sin \theta \sin \phi$.

So, you can see these are not that difficult, then let me **let me** write the expression for tangent of ϕ , so I divide this equation by this equation so I get tangent of ϕ becomes equal to $\frac{y}{x}$. So, this equation if I differentiate this, so we will get secant square, **secant square** $\phi \frac{d\phi}{dx}$ will be equal to if I differentiate this with respect to x , so this will be minus $\frac{y}{x^2}$; so this will be minus $\frac{y}{r \sin \theta r \sin \theta \sin \phi}$ divided by x^2 that is $r^2 \sin^2 \theta \cos^2 \phi$.

So, as you can see if I multiply secant square ϕ to $\cos^2 \phi$, it will become 1, so I obtain $\frac{d\phi}{dx}$ is equal to minus $\frac{1}{r \sin \phi \sin \theta}$, because $\sin \theta$ and $\sin^2 \theta$ one $\sin \theta$ cancels out; so this is one result, if I differentiate with respect to y that is very simple.

$\sec^2 \phi \frac{d\phi}{dy}$ will be just $\frac{1}{x}$, and $\frac{1}{x}$ is $\frac{1}{r \sin \theta \cos \phi}$, so if I multiply this one $\cos \phi$ will cancel out with secant ϕ and then $\cos \phi$ will come on the top; so I will have $\frac{1}{r \cos \phi \sin \theta}$ this is one expression and the last expression is that if I square these two.

So, $x^2 + y^2$ is $r^2 \sin^2 \theta$ $x^2 + y^2$ is $r^2 \sin^2 \theta$ and z^2 is $r^2 \cos^2 \theta$; so r^2 r^2 cancels out, so you are left with $\tan^2 \theta$ **sorry this is $\tan^2 \theta$** is equal to $\frac{x^2 + y^2}{z^2}$.

(Refer Slide Time: 09:55)

$$\tan^2 \theta = \frac{x^2 + y^2}{z^2}$$

$$2 \tan \theta \sec^2 \theta \frac{\partial \theta}{\partial x} = \frac{2x}{z^2} \Rightarrow \frac{2 r \sin \theta \cos \phi}{r^2 \cos^2 \theta}$$

$$\Rightarrow \frac{\partial \theta}{\partial x} = \frac{1}{r} \cos \theta \cos \phi$$

$$2 \tan \theta \sec^2 \theta \frac{\partial \theta}{\partial y} = \frac{2y}{z^2} = \frac{2 r \sin \theta \sin \phi}{r^2 \cos^2 \theta}$$

$$\frac{\partial \theta}{\partial y} = \frac{1}{r} \cos \theta \sin \phi$$

So, if we differentiate this with respect to x or y, let us **let us** differentiate with respect to x plus 2 tangent theta secant square theta delta theta by delta x is equal to 2 x by z square. So, this implies that **that** this is the right hand side is equal to 2 r sine theta cos phi and divided by r square cos square theta.

So, r square cos square theta this cos square theta and secant square theta cancel out and 2, 2 cancels out therefore, this implies that delta theta by delta x will be 1 over r the 2 also cancels out sine theta cos phi by tan theta **tan theta** is sine theta over cos theta, so this will be just cos theta cos phi. Finally if I differentiate with respect to y, then again two tangent of theta secant square theta delta theta by delta y this is equal to 2 y by z square that is 2 r sine theta sine phi divided by r square cos square theta.

Once again, this term will cancel out with this term and therefore, this will be delta theta by delta y will be equal to 1 over r cos theta sine phi, so we have now, expressions for delta r by delta y delta r by delta x delta theta by delta y delta theta by delta x delta phi by delta y and delta phi. So, I just have to substitute it here before we proceed further, let me tell you, let me warn you a little bit about the partial differentiation that you see; let us suppose I want to calculate delta r by delta x then y and z have to be remaining remain constant.

(Refer Slide Time: 12:58)

$$\frac{\partial r}{\partial x} \quad r^2 = x^2 + y^2 + z^2$$

$$2r \frac{\partial r}{\partial x} = 2x \Rightarrow \frac{\partial r}{\partial x} = \frac{x}{r}$$

$$\frac{\partial x}{\partial r} \quad x = r \sin \theta \cos \phi$$

$$\frac{\partial x}{\partial r} \bigg|_{\theta, \phi} = \sin \theta \cos \phi = \frac{x}{r}$$

$$\frac{\partial r}{\partial x} = \frac{\partial x}{\partial r} \quad \frac{dy}{dx} = 1$$

NPTEL

So therefore, I must express r in terms of x y z and now I differentiate with respect to x Δr by Δx becomes $2x$ and this becomes this gives Δr by Δx is equal to x by r . Now let us suppose I wanted to differentiate Δx by Δr , then I must express x because, when I differentiate with respect to r θ and ϕ remains constant. So, I must express x is equal to $r \sin \theta \cos \phi$ and if I differentiate this Δx by Δr and here, θ and ϕ remains constant; so this becomes $\sin \theta \cos \phi$ and this is also x by r , so you can see that Δr by Δx happens to be equal to Δx by Δr .

In total differential you know that dy by dx is equal to 1 over dx by dy but, in partial differentiation one has to be very careful as to when your differentiating partially with respect to x then y and z have to remain constant. And when your partially differentiating with respect to r then θ and ϕ are to remain constant, so these are some of the tricks therefore, the our objective was to calculate to obtain the operator representation of L_z in the Cartesian format it is $x \Delta \psi$ by Δy minus $y \Delta \psi$ by Δx .

But I wanted in terms of the polar coordinates and therefore, you have to evaluate this which we have evaluated all these are evaluated say for example, Δr by Δy is given here, Δr by Δx is given here, $\Delta \theta$ by Δy $\Delta \phi$ by Δy is given here, $\Delta \phi$ by Δx is given here (Refer slide time: 15:34), so everything is there

So, we just have to substitute those expressions in this carry out a simple manipulation and one finally, obtains this remarkable result that $L_z \psi$ becomes equal to minus $i \hbar$ cross $\Delta \psi$ by $\Delta \phi$.

(Refer Slide Time: 15:57)

$$L_z \psi = -i \hbar \frac{\partial \psi}{\partial \phi}$$

$$H \psi = E \psi$$

$$L_z \psi = \lambda \hbar \psi$$

$$-i \hbar \frac{\partial \psi}{\partial \phi} = \lambda \hbar \psi$$

$$\frac{\partial \psi}{\partial \phi} = i \lambda \psi \Rightarrow \psi = e^{i \lambda \phi}$$

$$L_z \psi = m \hbar \psi$$

$$m = 0, \pm 1, \pm 2, \dots$$

$$e^{i \lambda (\phi + 2\pi)} = e^{i \lambda \phi}$$

$$e^{i 2\pi \lambda} = 1$$

$$\lambda = m$$

$$m = 0, \pm 1, \pm 2, \dots$$

It simplifies to this particular relation, now let me **let me** try to find the Eigen values of L_z , so what is an Eigen value equation if you recall that the for the Hamiltonian the Eigen value equation is $H \psi$ is equal to $E \psi$ that is this is the operator operating on a wave function, E is a number multiplied by the same wave function, then this equation is known as the Eigen value equation.

So, I would like to find out say $L_z \psi$ the Eigen values and Eigen functions of the operator L_z , so let me write it down as let me try to solve Eigen value equation $\lambda \hbar$ cross i introduce \hbar cross just for the sake of simplicity $\Delta \psi$. So, $\lambda \hbar$ cross i **sorry** $L_z \psi$ is equal to minus \hbar cross i is just a constant $\Delta \psi$ by $\Delta \phi$, the Eigen value of the operator $x z$ I represent it by $\lambda \hbar$ cross the Eigen value of the Hamiltonian that we have been solving till now are the energy given by E .

So, this is equal to $\lambda \hbar$ cross ψ \hbar cross \hbar cross cancels out, if I multiply both sides by i then I get $\Delta \psi$ by $\Delta \phi$ is equal to $i \lambda \psi$, this is a very simple integration that ψ becomes the ϕ dependent. One cannot say anything about the θ or r dependent if ϕ dependent becomes e to the power of $i \lambda \phi$. Now, any wave function has to be well behaved, has to be single valued that is on the $x y$ plane you see

on the x y plane this is the angle phi if I go around the origin and I make phi 2 pi plus 2 pi I arrive at the same point and the wave function must have the same value.

So, therefore, **therefore**, e to the power of i lambda phi plus 2 pi must be equal to e to the power of i lambda phi therefore, we obtained the result that e to the power of i 2 pi lambda should be equal to plus 1 and therefore, from this we immediately obtain that lambda has to be equal to a positive or negative integer, lambda must be positive or negative integer, that m can take the values 0 plus minus 1 plus minus 2 and so on.

So the Eigen value of the operator L z are given by L z psi is equal to m h cross psi, where m is equal to 0 plus minus 1 plus minus 2 and so on. And what are the corresponding wave function.

(Refer Slide Time: 20:31)

Eigenvalue Equation

$$L_z \psi = m \hbar \psi \quad m=0, \pm 1, \pm 2, \dots$$

$$\Phi_m(\phi) = \psi(\phi) = \frac{1}{\sqrt{2\pi}} e^{im\phi}$$

$$\int_0^{2\pi} |\Phi_m(\phi)|^2 d\phi = 1 \quad \text{Normalization Condition}$$

$$\int_0^{2\pi} \Phi_{m'}^*(\phi) \Phi_m(\phi) d\phi = 0 \quad m \neq m' \quad \text{Orthogonality Condition}$$

NPTL

The **the** therefore, the solution of the Eigen value equation **the solution of the Eigen value equation** L z psi is equal to m h cross psi, where m will take the values 0 plus minus 1 plus minus 2, etcetera.

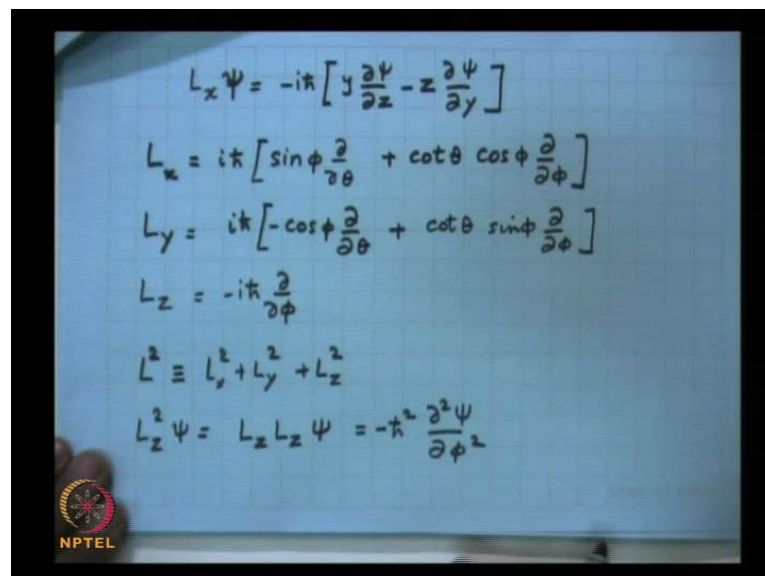

And the corresponding phi dependence the phi dependence only one cannot say anything about the r and the theta will be e to the power of i m phi and to normalize it you will have under root of 2 pi, these wave functions are usually denoted as capital phi subscript m as phi.

And because of this normalization constant if you have $\int_0^{2\pi} \psi^* \psi d\phi$ from 0 to 2π ψ goes from 0 to 2π this will be one this is known as the normalization condition. And the second is that if you have 0 **this is** this can be also true that very easily $\int_0^{2\pi} \psi^* \psi d\phi$ this will be 0 for $m \neq m'$ this is known as the orthogonality condition.

So therefore, we have been able to find that the operator L_z we have been able to solve this equation L_z has the Eigen values $m \hbar$ cross multiples of \hbar cross, that m can take we have used the condition, **that the wave functions have to be single valued**, that the wave functions have to be single valued that as I go from the point ϕ to $\phi + 2\pi$ the wave function was remained unchanged.

Using this single valued condition, the fact that the wave function should be single valued we obtained λ should be either a positive or a negative integer or a 0 (Refer slide time: 23:11), so these are the so what are the Eigen values of the operator L_z . The Eigen values are $m \hbar$ cross that m is equal to 0 plus minus 1 plus minus 2, etcetera; now we have obtained the operator representation of the operator L_z exact very similarly, you can obtain for L_x and L_y .

(Refer Slide Time: 23:39)

$$L_x \psi = -i\hbar \left[y \frac{\partial \psi}{\partial z} - z \frac{\partial \psi}{\partial y} \right]$$

$$L_x = i\hbar \left[\sin\phi \frac{\partial}{\partial \theta} + \cot\theta \cos\phi \frac{\partial}{\partial \phi} \right]$$

$$L_y = i\hbar \left[-\cos\phi \frac{\partial}{\partial \theta} + \cot\theta \sin\phi \frac{\partial}{\partial \phi} \right]$$

$$L_z = -i\hbar \frac{\partial}{\partial \phi}$$

$$L^2 \equiv L_x^2 + L_y^2 + L_z^2$$

$$L_z^2 \psi = L_x L_z \psi = -\hbar^2 \frac{\partial^2 \psi}{\partial \phi^2}$$

So, L_x as you know will be L_x operating on ψ will be minus $i \hbar$ cross $y p_z$, that is $y \Delta \psi / \Delta z$ minus $z p_y$ that is $\Delta \psi / \Delta y$. And again you expressed this in terms of spherical polar coordinates and if you do that algebra then, you obtain a

slightly combustion just it is not at not combustion just a little detailed algebra one has to keep track of the factors; i h cross sine phi delta by delta theta plus cot theta cos phi delta by delta phi. And L y is equal to i h cross minus cos phi delta by delta theta plus cot theta sine phi delta by delta phi and of course, we had obtained that L z is equal to minus i h cross delta by delta phi.

Now, I want an operator presentation of L square and L square is defined as L x square plus L y square plus L z square L z square is very easy to obtain, let me do this L z square psi square of **of** an operator is just L z operating on L z tab psi. So, if you do that this will be minus h cross's square delta 2 psi by delta phi square del by del phi and then again del by del phi but, for others it is not that simple but, fairly straight forward.

(Refer Slide Time: 25:57)

The image shows handwritten mathematical derivations for the squared angular momentum operators acting on a wavefunction ψ . The derivations are as follows:

$$L_x^2 \psi = -\hbar^2 \left[\sin^2 \theta \frac{\partial^2 \psi}{\partial \phi^2} + 2 \sin \theta \cos \theta \frac{\partial \psi}{\partial \phi} \frac{\partial}{\partial \theta} + \cos^2 \theta \frac{\partial^2 \psi}{\partial \theta^2} \right]$$

$$L_y^2 \psi = -\hbar^2 \frac{\partial^2 \psi}{\partial \phi^2}$$

$$L_z^2 \psi = -\hbar^2 \left[\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial \psi}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2 \psi}{\partial \phi^2} \right] = \lambda^2 \psi$$

An NPTEL logo is visible in the bottom left corner of the slide.

So, L x square will be L x square psi I will just write down the expression that will be equal to minus h cross's square. And then you will have sine phi delta by delta theta plus cot theta cos phi del by delta phi, this is L x times L x that is sine phi delta psi by delta theta plus cot theta cos phi delta by delta psi by delta phi.

When I will operate this on this, operate this on this, operate this on this, operate this (Refer slide time: 26:46) and we have to be very careful, when we differentiate with respect to theta then of course, phi can be kept constant, so if I operate this on this the first term will be very simple sine square phi sine square phi delta 2 psi by delta theta square. But, when we operate this on this whereas, there is a tail here, depending on theta

so one has to be a little careful. Similarly, I can it is advisable that you do this once and it will allow you to get used to the way in which one deals with these operator algebra.

Similarly, one can calculate L_y square and we are already L_z square psi which was the easiest to calculate which was $\hbar^2 \sin^2 \theta \frac{\partial^2 \psi}{\partial \phi^2}$, if you add this up then, surprisingly this L^2 square psi which is L_x^2 square plus L_y^2 square plus L_z^2 square; this comes out to be minus $\hbar^2 \sin^2 \theta \frac{\partial^2 \psi}{\partial \phi^2}$ plus $\frac{1}{\sin^2 \theta} \frac{\partial}{\partial \theta} \left(\sin^2 \theta \frac{\partial \psi}{\partial \theta} \right)$ plus $\frac{1}{\sin^2 \theta} \frac{\partial^2 \psi}{\partial \phi^2}$.

So, this is the expression that comes out for the operator L^2 square, now our object is to find the we have found out the Eigen values and Eigen functions of the operator L_z and that was very simple we have found out that **that** the Eigen values (Refer slide time: 28:59). Eigen values of $m \hbar$ cross and the Eigen functions of $\frac{1}{\sqrt{2\pi}}$ to the power of i and ϕ . Our next step which is not that easy is to find out the Eigen values and Eigen functions of the operator L^2 square.

So, I write this down as equal to $\lambda \hbar^2 \sin^2 \theta \psi$ and I want to solve this, so I our objective now, is to solve this particular equation I have introduced $\hbar^2 \sin^2 \theta$ for the sake of convenience. So, the $\hbar^2 \sin^2 \theta$ square, $\hbar^2 \sin^2 \theta$ square which are constants gets cancelled and I bring this term to the left hand side.

(Refer Slide Time: 29:54)

$$\frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin^2 \theta \frac{\partial \psi}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2 \psi}{\partial \phi^2} + \lambda \psi(\theta, \phi) = 0$$

$$\psi(\theta, \phi) = F(\theta) \Phi(\phi)$$

$$\frac{\Phi(\phi)}{\sin \theta} \frac{d}{d\theta} \left(\sin^2 \theta \frac{dF}{d\theta} \right) + \frac{F(\theta)}{\sin^2 \theta} \frac{d^2 \Phi}{d\phi^2} + \lambda F \Phi = 0$$

$$\times \frac{\sin^2 \theta}{F \Phi}$$

$$\frac{1}{F(\theta)} \sin^2 \theta \frac{d}{d\theta} \left(\sin^2 \theta \frac{dF}{d\theta} \right) + \lambda \sin^2 \theta = - \frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2} = m^2$$

NPTEL

So I obtain $\frac{1}{\sin^2 \theta} \frac{d}{d\theta} \left(\sin^3 \theta \frac{d\psi}{d\theta} \right) + \frac{1}{\sin^2 \theta} \frac{d^2 \psi}{d\theta^2} + \lambda \psi = 0$ I want to solve this equation. Our objective is to find this value of λ and the corresponding wave functions that is a very important problem. Now, we use the same method of separation of variables ψ of θ and ϕ , we write down as $f(\theta)$ multiplied by $\Phi(\phi)$ $\psi = f(\theta)\Phi(\phi)$ this is ψ square.

So, I substitute this, so I get if I substitute it here, let me do it step by step $\Phi(\phi)$ divided by $\sin^2 \theta$ and now, I can write it total differentiate $\frac{d}{d\theta} \left(\sin^3 \theta \frac{dF}{d\theta} \right) + \frac{1}{\sin^2 \theta} \frac{d^2 F}{d\theta^2} + \lambda F = 0$ So, F will come outside, now $F(\theta)$ $\sin^2 \theta \frac{d^2 \Phi}{d\phi^2} + \lambda F \Phi = 0$ have the variable separated out not yet.

If this involves ϕ and θ this involves ϕ and θ this involves ϕ and θ (Refer slide time: 32:03) but, what we do is let me, multiply the whole equation by $\sin^2 \theta$ divided by $F \Phi$. So, please see if I multiply the whole equation, then I get $\frac{1}{F} \frac{d}{d\theta} \left(\sin^3 \theta \frac{dF}{d\theta} \right) + \frac{1}{F} \frac{d^2 F}{d\theta^2} + \lambda \sin^2 \theta = -\frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2}$ because Φ this Φ will cancel out with this $\frac{1}{F} \sin^2 \theta$ by $\sin^2 \theta$ that is $\frac{d}{d\theta} \left(\sin^3 \theta \frac{dF}{d\theta} \right) + \frac{1}{F} \frac{d^2 F}{d\theta^2} + \lambda \sin^2 \theta$ what I will do is; I will write this term first and take this term to the right hand side. So, I write $\lambda \sin^2 \theta = -\frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2}$ λ is assumed to be to a function of θ .

So, now as you can see the variables have indeed separated out the left hand side is a function of θ the right hand side is a function of ϕ only, so a function of θ cannot be equal to a function of ϕ unless both of them are equal to a constant. So, I put this equal to $-m^2$ a square of number and the reason is that it will come out in a moment.

(Refer Slide Time: 34:27)

$$\frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2} + m^2 = 0 \Rightarrow \frac{d^2 \Phi}{d\phi^2} + m^2 \Phi(\phi) = 0$$
$$\boxed{\Phi_m(\phi) = \frac{1}{\sqrt{2\pi}} e^{im\phi}}; \quad m = 0, \pm 1, \pm 2, \dots$$

For $\Phi(\phi)$ to be single valued $m = 0, \pm 1, \pm 2, \dots$

$$e^{im\phi} = e^{im(\phi + 2\pi)}$$
$$e^{i2\pi m} = 1$$

So, let me solve this part first, so this part will come out if I just look at the phi part, so I obtain $\frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2} + m^2 = 0$ this will imply $\frac{d^2 \Phi}{d\phi^2} + m^2 \Phi = 0$. The solution of this is extremely simple we have Φ is equal to $e^{im\phi}$ and as we have just discussed few minutes back if I want for the wave function to be single valued m must be equal to 0 plus minus 1 plus minus 2, etcetera.

That is if you increase ϕ to $\phi + 2\pi$, it must give me the same wave function that is $e^{im\phi}$ must be equal to $e^{im(\phi + 2\pi)}$, as I increase ϕ by 2π , I get the same value of the function; otherwise the wave function will be multiple value. So, you will have $e^{i2\pi m} = 1$ and therefore, m must be 0 plus minus 1 plus minus 2, etcetera. So we have found one part of the solution and to normalize it I form an orthonormal set of complete set of orthonormal wave functions.

So, these are which we had obtained, these are also Eigen functions of the L_z operator the Eigen function of the L_z operator m is equal to 0 plus minus 1 plus minus 2, etcetera. So, we come back to the equation and we find that m^2 must be the square of this integer can I put this as a negative constant the answer is of course, we can but, if you

solve this then the solutions will be on the form of e to the power of $m\phi$ which are not single value function.

And so therefore, this has to be put equal to a positive constant if I put into a negative minus m square, then the solution will be exponential and those will not be single valued. So therefore, once we have solved the ϕ part of the equation rigorously, now let me solve the θ part of the equation, so we have here.

(Refer Slide Time: 37:54)

$$\frac{\sin\theta}{F} \frac{d}{d\theta} \left(\sin\theta \frac{dF}{d\theta} \right) + \lambda \sin^2\theta - m^2 = 0$$

$$\times \frac{F(\theta)}{\sin^2\theta} : \frac{1}{\sin\theta} \frac{d}{d\theta} \left(\sin\theta \frac{dF}{d\theta} \right) + \left(\lambda - \frac{m^2}{\sin^2\theta} \right) F(\theta) = 0$$

$$\underline{m=0}$$

$$\frac{1}{\sin\theta} \frac{d}{d\theta} \left(\sin\theta \frac{dF}{d\theta} \right) + \lambda F(\theta) = 0$$

$$x = \cos\theta$$

$$\sin\theta \frac{dF}{d\theta} = -\frac{dF}{dx} \sin^2\theta = -\frac{dF}{dx} (1-x^2)$$

$$\frac{d}{dx} \left[(1-x^2) \frac{dF}{dx} \right] + \lambda F(x) = 0 \quad \text{Legendre's equation}$$

So, let me write the θ part of the equation and it will be something like this, so minus m square, so sine θ divided by F of θ d by $d\theta$ sine θ dF by $d\theta$ plus lambda sine square θ minus m square is equal to 0. I multiply the above equation by F of θ divided by sine square θ and I will get 1 over sine θ d $d\theta$ of sine θ dF by $d\theta$ plus lambda minus m square by $\sin^2\theta$ sine square θ F of θ equal to 0; this is known as the **associated Legendre equation** associated Legendre equation.

The solution of this equation is little complicated but, of course, people have found the solution, what we will do is find the solution for m equal to 0; for m equal to 0 for m equal to 0 the above equation becomes 1 over sine θ d $d\theta$ of sine θ dF by $d\theta$ plus lambda F of θ equal to 0.

Now I introduce a new variable x which is defined to be equal to $\cos \theta$, so I write this in terms of this, so dF by $d\theta$ will be equal to dF in terms of the x variable $x \frac{dF}{dx}$ by $d\theta$, that is $-\sin \theta$. So, if I multiply by $\sin \theta$, so then this becomes $\sin^2 \theta$ and that is equal to $1 - x^2$ and then you can calculate what is $\frac{d^2 F}{dx^2}$, I have just done that.

And final result will be that $\frac{d}{dx} \left((1-x^2) \frac{dF}{dx} \right) + \lambda F(x) = 0$, this is very simple this is known as the Legendre's equation; which you must have studied but, in any case, we will obtain the solution of this particular equation.

(Refer Slide Time: 41:22)

The image shows a handwritten derivation of Legendre's equation. At the top, the equation is written as $(1-x^2) \frac{d^2 F}{dx^2} - 2x \frac{dF}{dx} + \lambda F(x) = 0$, labeled "Legendre Equation". Below this, it is noted that $x = \cos \theta$ and $-1 \leq x \leq 1$. The "Power Series" method is introduced, assuming $F(x) = \sum_{r=0,1,\dots}^{\infty} a_r x^{r+s}$, labeled "Frobenius method". The equation is then substituted with the series, leading to $(1-x^2) \sum a_r (r+s)(r+s-1) x^{r+s-2} - 2x \sum a_r (r+s) x^{r+s-1} + \lambda \sum a_r x^{r+s} = 0$. This is simplified to $\sum a_r (r+s)(r+s-1) x^{r+s-2} - \sum a_r [(r+s)(r+s-1) + 2(r+s) - \lambda] x^{r+s-1} = 0$. The final result is $(r+s)(r+s+1) - \lambda = 0$.

We rewrite the first the Legendre's equation, we differentiate the first term we obtain $1 - x^2$ $\frac{d^2 F}{dx^2}$ and the differentiation is $-2x \frac{dF}{dx} + \lambda F(x) = 0$, this is also another form of the Legendre equation; here as we know that x is equal to $\cos \theta$ And therefore, x lies between plus 1 and minus 1. Now, we solve this Legendre's equation **by the power series method**, by the power series method which is also known as the Frobenius method.

And we assume a solution of the form $F(x)$ is a sum $a_r x^{r+s}$ and the summation is over r , r goes from 0, 1, 2 to infinity this power series method which we had encountered while, solving the confluent hyper geometric equation is one of the very powerful methods for solving a second order differential equation.

This is also known as the Frobenius **frobenius** method, now I substitute the solution in this differential equation, so I will get $1 - x^2$ and if I differentiate this equation this expression twice. So, I will get a r first differentiation will give me $r + s$ and the second differentiation will give me $r + s - 1$ x to the power of $r + s$ $r + s - 2$ and the summation is over r from 0 to infinity $- 2x$ and if I differentiate this once.

So, you will get a r into $r + s$ into x raise to the power of $r + s - 1$ plus λ and summation $a_r x$ to the power of $s + r$ is equal to 0 as you can see if I multiply x here so this becomes $r + s$ and if I multiply x^2 here so this again becomes $r + s$, so essentially we have two terms first I multiply one by this, so I obtain this expression only.

So, summation $a_r r + s$ into $r + s - 1$ x raise to the power of $r + s - 2$ minus and if I take to the other side or let me put the minus sign here, minus a_r , now if I multiply x^2 here, as I just now mention becomes x raise to the power $r + s$. So, it becomes $r + s$ into $r + s - 1$ and I have taken the minus sign out. So, this is plus 2 into $r + s$ and since I have taken the minus sign outside, so this is minus λ **minus lambda** into x raise to the power of $s + r$ is equal to 0 .

So, now this expression if you take $r + s$ outside, so this becomes $r + s$ multiplied by $r + s - 1 + 2$, so this becomes $r + s + 1 - \lambda$ and so since this minus this is 0 , so I take to the other side of the **of the** equation.

(Refer Slide Time: 46:10)

$$\begin{aligned}
 & \sum_{r=0,1,\dots}^{\infty} a_r (r+s)(r+s-1) x^r = \sum_{r=0}^{\infty} a_r [(r+s)(r+s+1) - \lambda] x^{r+2} \\
 & a_0 s(s-1) + a_1 (s+1)s x + \sum_{r=0}^{\infty} a_{r+2} (r+s+2)(r+s+1) x^{r+2} = \sum_{r=0}^{\infty} a_r [(r+s)(r+s+1) - \lambda] x^{r+2} \\
 & a_0 s(s-1) = 0 \\
 & a_1 (s+1)s = 0 \quad \frac{a_{r+2}}{a_r} = \frac{(r+s)(r+s+1) - \lambda}{(r+s+2)(r+s+1)} \checkmark \\
 & \boxed{s=0} \text{ Root of the IE which will determine both solutions}
 \end{aligned}$$

So, I will obtain **I will obtain** summation and let me multiply the equation the entire equation, we multiply entire equation by x to the power of 2 minus x , so the left hand side becomes summation $a_r r$ plus s r plus s minus 1 into x to the power of r , because I multiplied by x raise to the power 2 minus s . So, this term goes off so r is equal to 0, 1 to infinity and in my right hand side, becomes $a_r r$ plus s this term plus r plus s minus 1 plus 1 minus λ times x raise to the power of r plus 2; because I have multiplied by x raise to the power of 2 minus s so this becomes like this.

So, both the sums are from 0 to infinity, now this equation as we have mentioned earlier is valid for all values of x , so I make an expansion, so the first term is a 0 r equal to 0 s into s minus 1 x to the power of 0 plus a 1 **a 1** s plus 1 into x multiplied by x and then we will have plus summation a_{r+2} , I replace r by r plus 2; so then r goes from 0 to infinity you say I have taken out the first two terms outside.

So, r plus 2 that means r plus s plus 2 and r plus s plus 1 x to the power of r plus 2, this is equal to the same, what is written above that is summation r equal to 0 to infinity $a_r r$ plus s the same term, within brackets r plus s plus 1 minus λ multiplied by multiplied by x raise to the power of r plus 2.

Now, each term the coefficient this is an equation which has to be valid for all values of x , so the coefficient of x to the power of 0 must be 0 coefficient of x to the power 1 must be 0, coefficient of x to the power 2 must be 0 and so on.

So, the first term gets a 0 s into s minus 1 must be equal to 0, the second term will give a 1 s plus 1 into s is equal to 0 and the third term will get a r plus 2 multiplied by this will be equal to a r multiplied by this; so I obtain a r plus 2 divided by a r will be equal to r plus s r plus s plus 1 minus lambda divided by r plus s plus 2 into r plus s plus 1, this is known as the recurrence relation, because using this equation I can determine a r plus 2 in terms of a r.

Now, in this equation there are two roots s is equal to 0 and s is equal to 1 and the root s is equal to 0 makes a 1 indeterminate; so there is a theorem in the theory of differential equation that is one of the roots makes a 1 indeterminate, then that particular root is the root s equal to 0 will determine both the solution.

So, this is the root of the indicial equation, which will determine which will determine both solutions and we will show this in a moment, so we will just assume s is equal to 0 and if I assume s is equal to 0, then my recurrence relation becomes very simple.

(Refer Slide Time: 51:34)

The image shows a handwritten derivation on a grid background. At the top, the recurrence relation is given as $\frac{a_{r+2}}{a_r} = \frac{r(r+1) - \lambda}{(r+2)(r+1)}$, with the text "Recurrence Relation" written to the right. Below this, the function $F(x)$ is expressed as a sum of two series: $F(x) = [a_0 + a_2 x^2 + a_4 x^4 + a_6 x^6 + \dots] + [a_1 x + a_3 x^3 + \dots]$. Then, the limit $\lim_{r \rightarrow \infty} \frac{a_{r+2}}{a_r} \rightarrow 1$ is shown, followed by the expression $a_{100} x^{100} [1 + x^2 + x^4 + x^6 + \dots]$ with $x = \pm 1$ written below it. Finally, the indicial equation $\lambda = l(l+1)$ is written, with $l = 0, 1, 2, \dots$ and a specific value $\lambda = 6$ noted below.

So, if I substitute s is equal to 0, then the recurrence relation will become a r plus 2 a r is equal to r into r plus 1 minus lambda divided by r plus 2 multiplied by r plus 1. Since a 0 will be related to a 2 and a 2 will be related to a 4 and so on we will have therefore. So, this is the recurrence relation, this is the recurrence relation and this is the root of the indicial equation; so my solution will be the solution F of x can be written as like this two independent solutions, the first term consists of only even powers a 2 x square plus a

4 x 4 plus a 6 x 6 only the even powers plus a 1 x plus a 3 x cubed plus a 5 x 5 and so on; Because a 2 is related to a 0 a 4 is related to a 2.

So, we have the **odds** even series and then we have the odd series, now we can see **from this** from the recurrence relation that as r tends to infinity for large terms this the dominating terms becomes r square the dominating terms in the denominator becomes r square.

So, a r plus 2 divided by r square tends to 1, so they are equal, so if I choose a larger value of r that is suppose x to the power of 100, then beyond that and the coefficients are equal; that means, let us suppose after x to the power of 100 I can write this down that a 100 and then it will be 1 plus x square plus x 4 plus x 6 this is a divergence series of x equal to plus minus 1. And therefore, it will be of at x equal to plus minus 1 the divergence at x equal to plus 1 and so therefore, for the solution to be well behaved we must make terminate the series, we must **we must** turn this infinite series to a polynomial and that will happen if λ is equal to L into L plus 1, if λ is equal to L plus 1.

That is L equal to 0, 1, 2, 3 then and then only will the will one of the infinite series become a polynomial, let me illustrate this; let us suppose I take L equal to 2, so λ is equal to 6 and therefore, we will have **we will have** from here, if λ is equal to 6.

(Refer Slide Time: 55:32)

$$\frac{a_{r+2}}{a_r} = \frac{r(r+1)-6}{(r+2)(r+1)}$$

$$\frac{a_2}{a_0} = \frac{-6}{2} = -3$$

$$\frac{a_4}{a_0} = 0$$

$$F(x) = a_0 + a_2 x^2 + a_4 x^4 + \dots$$

$$= a_0 [1 - 3x^2]$$

$$P_2(x) = \frac{1}{2} (3x^2 - 1)$$

$$P_2(1) = 1$$

$P_2(x)$
 $P_2(1) = 1$

NPTEL

So, then we will have a r plus 2 divided by a r is equal to r into r plus 1 minus 6 divided by r plus 2 into r plus 1 and let me take the just the even series, so a 2 by a 0 that is r a 0. So, this becomes minus 6 r is 0 so 2, so this is equal to minus 3 and a 4 by a 0 will be equal to r s 2. So, 2 into 3 6 minus 6, so this is 0 therefore, the **the** even series, become a polynomial and we will have a 0. So F of x the even series will become a 2 plus a 2 x square plus a 4 x 4, so a 0 is a 0, let us suppose and a 2 by a 0 is 1 minus 3 x square plus a 4 is 0; so this is the polynomial solution.

And the polynomial solution is known as the Legendre polynomials, p_1 of x we assume that p_1 at x equal to 1 is 1, if I do that then p this becomes this p_2 of x this becomes 3 x square minus 1 divided by 2. When we have chosen the value of a 0, such that at x equal to 1 p_2 of 1 is 1; so we will continue from this point onwards in my next lecture.
