**The Two Body Problem**

(Refer Slide Time: 00:46)

Handwritten notes on a green board showing the derivation of the radial Schrödinger equation for a hydrogen-like atom. The notes include the potential energy function  $V(r) = -\frac{Ze^2}{r}$ , the radial equation in terms of  $u(r)$ , the substitution  $u(r) = r^{\ell+1} e^{-\lambda r/2} y(r)$ , and the resulting equation for  $y(r)$  which is solved using the confluent hypergeometric function (CHGE) to give  $y(x) = {}_1F_1(a, c, x)$ .

In our previous lecture, we had solved the hydrogen like atom problem, which was the simplest example of a two body problem, and we were considering two particles  $m_1$  and  $m_2$ ;  $m_2$  would represent usually the electron,  $m_1$  will have a charge of  $Ze$ , and the potential energy function, was given by minus  $Ze^2$  by  $r$ , where  $Ze$  is the charge of the nucleus. We found that the radial part of the Schrödinger equation, could be written as  $\frac{d^2 u}{dr^2} + \left[ -\frac{1}{4} + \frac{\lambda}{r} - \frac{\ell(\ell+1)}{r^2} \right] u(r) = 0$  since the energy was negative,  $0 < r < \infty$ . We found that the radial part of the Schrödinger equation, could be written as  $\frac{d^2 u}{dr^2} + \left[ -\frac{1}{4} + \frac{\lambda}{r} - \frac{\ell(\ell+1)}{r^2} \right] u(r) = 0$ . We found that the radial part of the Schrödinger equation, could be written as  $\frac{d^2 u}{dr^2} + \left[ -\frac{1}{4} + \frac{\lambda}{r} - \frac{\ell(\ell+1)}{r^2} \right] u(r) = 0$ .

Now, we studied the small  $r$  behavior of this equation, and the large  $r$  behavior. That suggested that we should try out a solution of this form,  $u$  of  $r$  is equal to  $r$  to the power of  $\ell + 1$ , minus  $r$  by 2, times  $y$  of  $r$ . Now, there is no approximation here,

because I have defined  $y$  of  $\rho$  by this equation. Then, we found that if we use this, then  $y$  of  $\rho$  satisfies the following differential equation;  $\rho \frac{d^2 y}{d\rho^2} + (2l + 1 - \rho) \frac{dy}{d\rho} + (\lambda - l - 1) y = 0$  (Refer Slide Time: 02:37).

Now, if you would recollect some lectures back, we had discussed the confluent hypergeometric equation; confluent hypergeometric equation which was  $x \frac{d^2 y}{dx^2} + (c - x) \frac{dy}{dx} - a y = 0$ . So, this tells us, that this equation is also a confluent hypergeometric equation. Of course, the independent variable is  $\rho$  now, but  $c$  is equal to  $2l + 1$ , and  $a$ , is equal to  $l + 1 - \lambda$ . The well behaved, we have studied this equation in great detail. The well behaved solution of this,  $y$  of  $x$  at the origin, you must remember that  $\rho$  was equal to  $\gamma r$ , and  $r$  is the spherical polar coordinate, so  $r$  goes from 0 to infinity; not minus infinity to plus infinity.

So,  $r$  goes from 0 to infinity. So,  $y$  of  $x$  was one of the solutions is  $F(1, 1, x)$ , the well behaved solution is  $e^{-x}$ .

(Refer Slide Time: 04:45)

$$y(x) = {}_1F_1(a, c, x) = 1 + \frac{a}{c} \frac{x}{1!} + \frac{a(a+1)}{c(c+1)} \frac{x^2}{2!} + \frac{a(a+1)(a+2)}{c(c+1)(c+2)} \frac{x^3}{3!} + \dots$$

$$\rightarrow e^x x^{a-c} e^{-x}$$

$$u(\rho) = \rho^{l+1} e^{-\rho/2} y(\rho)$$

$$e^{\rho/2}$$

$$a = 0, -1, -2, \dots = -n_r$$

$$n_r: \text{radial quantum number}$$

$$a = l + 1 - \lambda = -n_r$$

$$\lambda = l + 1 + n_r \quad ; \quad l = 0, 1, 2, \dots$$

$$\lambda = n \quad \text{Total quantum number}$$

$$n = 1, 2, 3, \dots$$

The well behaved solution is  $y$  of  $x$  is equal to  $F(1, 1, x)$ . This is the confluent hypergeometric function, and the series representing that, is very easy to remember; one plus  $a$  by  $c$ ,  $x$  by 1 factorial, plus  $a$  into  $a + 1$  divided by  $c$  into  $c + 1$ ,  $x$  square by 2

factorial, plus  $a$  into  $a + 2$ , plus  $1$ ,  $a + 2$  and so on,  $c$  into  $c + 1$  into  $c + 2$  etcetera,  $x$  cube by factorial three and so on.

Now, assume, as I had disused earlier, if  $a$  is equal to  $c$ , then this is just the series of  $e$  to the power of  $x$ . So, although the infinite series is convergent, but it blows up at infinity as  $e$  to the power of  $x$ . I repeat, although this infinite series is convergent, it blows up, it converges to a very large value for a large values of  $x$ .

So, in fact, the asymptotic form of  $F_1 c$ , this is  $x$  to the power of  $a - c$  into  $e$  to the power of  $x$ . Now, you may recall that my  $u$  of  $\rho$  function was  $\rho$  to the power of  $l + 1$ ,  $e$  to the power of  $-\rho$  by  $2$   $y$  of  $\rho$ . Now, at large values of  $\rho$ , this will behave as  $a$  to the power of  $\rho$ . So, this multiplied by this, will become  $e$  to the power of  $\rho$  by  $2$  and so although the infinite series is convergent, the wave function will blow up and that cannot happen. The wave function can otherwise it will not be normalizable.

So, it can be reduced to a polynomial only if  $a$  is  $0$  or  $-1$  or  $-2$  etcetera. So, we put this as  $-n$  of  $r$ , where  $n$  of  $r$  is known as the radial quantum number. Radial quantum number therefore, we have, if we recall that we had here in this paper (Refer Slide Time: 07:53) the differential equation that we had obtained was the confluent hypergeometric equation with  $c$  is equal to  $2l + 2$  and  $a$  is equal to  $l + 1 - \lambda$ .

So, we have now shown that for the solution to be well behaved,  $a$  must be  $0$  or a negative integer or I write that as  $-n_r$ . Since,  $a$  is equal to  $l + 1 - \lambda$ . So, this is equal to  $-n_r$ . Please see this; I take  $\lambda$  to this side and  $n_r$  to this side. I get  $\lambda$  is or is equal to  $l + 1 + n_r$  where  $n_r$  goes from  $0, 1, 2, 3$  to infinity, so this is because of  $l$  also, if you recollect  $l$  is equal to  $0, 1, 2, 3$  etcetera.

This I write is equal to  $n$ , which is known as the total quantum number, and  $n$  can only take values;  $n$  can only take values of  $1, 2, 3, 4$  etcetera. So, this is my total quantum number, so we have proved that for the wave function to be well behaved that is for the wave function not to blow up at infinity,  $\lambda$  must be equal to an integer, and if you recall that  $\lambda$  was equal to  $2\mu e^2$  by  $h^2$  cross  $\gamma$ .

(Refer Slide Time: 10:00)

The image shows a greenboard with handwritten mathematical derivations for the Bohr model. The equations are as follows:

$$\lambda = \frac{2\pi Z e^2}{h^2 \gamma} = n$$

$$\frac{4\pi^2 Z^2 e^2 \alpha^2 h^2 c^2}{h^2} = n^2 \left( -\frac{8\pi^2 E}{h^2} \right)$$

$$E = E_n = -\frac{\mu Z^2 \alpha^2 c^2}{2 n^2}$$

Below the equation for  $E$ , there are three examples of  $Z$  values:

- $Z=1$  (Hydrogen)
- $Z=2$  (Helium ion,  $\text{He}^+$ )
- $Z=1$  (Hydrogen)

On the right side of the board, the following equations are written:

$$\frac{2\pi E}{h^2 \gamma^2} = -\frac{1}{4}$$

$$\gamma^2 = -\frac{8\pi^2 E}{h^2}$$

$$\frac{e^2}{hc} = \alpha$$

$$\alpha \approx \frac{1}{137}$$

$$c \approx 3 \times 10^8 \text{ m/s}$$

$$n = 1, 2, \dots$$

$$Z = 1$$

So, we write this down as this. Please, see this lambda was equal to  $2\pi Z e^2$  by  $h^2 \gamma$ . This must be equal to  $n$  and  $2\pi E$  by  $h^2 \gamma^2$  square. We have put equal to minus 1 by 4, so  $\gamma^2$  was equal to minus  $8\pi^2 E$  by  $h^2$  cross square.

So, if I square this, which is very easy,  $4\pi^2 Z^2 E^4$ . Now, I will do one more simplification,  $e^2$  by  $h^2 c$  is equal to  $\alpha$ . So, this will be  $e^2$  therefore,  $\alpha^2$ ,  $h^2$  cross square,  $c^2$  square divided by, I have square this, so  $4\pi^2 Z^2 \alpha^2 h^2 c^2$  divided by  $h^2$  cross to the power of 4,  $n$  is equal to  $n^2$ ,  $\gamma^2$  square, so  $\gamma^2$  square is minus  $8\pi^2 E$  by  $h^2$  cross square.

Please see this; we have to do this little carefully. So,  $h^2$  cross square multiplied by  $h^2$  cross square by  $h^2$  cross 4. These two terms we will cancel out. 1  $\mu$  will cancel out with 1  $\mu$  and 4 divided by 8 is  $n^2$ . So, I will get  $E$  is equal to  $E_n$  is equal to minus 4, this becomes two, so  $2 n^2$ ,  $\mu Z^2$ ,  $\alpha^2 c^2$ .

You must check the dimensions.  $\alpha$  is a dimensionless parameter,  $Z^2$  is dimensionless,  $m c^2$  square, as you know from Einstein's equation,  $m c^2$  square is the energy. So, this is energy so that is alright.

So, this quantity is, therefore, these are the discrete energy states of the hydrogen atom and it is a remarkable time of the Schrödinger equation. Schrödinger obtained this in his very first paper in 1926. He wrote down the equation; he wrote a series of three papers on and which gave birth to the field of quantum mechanics or wave mechanics and in one of the papers, he introduced the Schrödinger equation and there he solved it for the hydrogen atom problem, and he obtain the discrete Eigen values from the solution of a differential equation. This is considered to be one of the greatest times of quantum mechanics.

From the solution of differential equation, one obtained the energy Eigen values of the hydrogen atom, which compared extremely well with the experimental data; the Balmer series, the Lyman series, the Paschen series. So, here you can see  $\mu$  is the reduced mass, so as I had mentioned that for the hydrogen atom  $m_e$  is the electron mass and  $m_p$  is the proton mass.

So, for the hydrogen atom  $\mu_h$  is equal to, you may write it down if you feel like,  $m_e m_p$  by  $m_e + m_p$  which is  $9.1045 \times 10^{-31} \text{ kg}$  and  $\alpha$  as we know is about  $1/137$ ,  $c$  is approximately  $3 \times 10^8 \text{ m/s}$  and  $n$  can take values of 1, 2, 3 and for the hydrogen atom  $z$  is equal to 1. For the deuterium atom  $z$  is equal to 1, because the hydrogen atom is one proton and one electron, the deuterium atom is one proton and one neutron and the electron.

Here, also  $z$  is equal to 1 for the deuterium atom, for the helium atom the nucleus consists of the alpha particle, two protons and two neutrons. So,  $z$  is equal to 2 for the helium plus simply ionized helium atom has  $z$  is equal to 2 and of course, the mass of the nucleus is slightly different so that the reduced mass is different. Therefore, we will have so, these are the energy Eigen values and if you substitute it, substitute the values of  $\mu$  that I wrote down and  $\alpha$  that I wrote down and  $c$  etcetera and if I assume  $z$  to be 1.

(Refer Slide Time: 16:04)

So, you get the lines, energy levels corresponding to the hydrogen atom. So, in a transition say from  $n$  is equal to  $n_1$  to  $n$  is equal to  $n_2$ , when an atom makes a transition characterized by the total quantum number  $n_1$  to a total quantum number  $n_2$ , a photon is emitted corresponding to the appropriate frequency or wave length.

So, when  $n_2$  is 1, and  $n_1$  is 2, 3, 4 etcetera, you get what is known as the Lyman series. When  $n_2$  is 2 and  $n_1$  is 3, 4, 5, 6, 7, 8 etcetera you get the Balmer series, and  $n_2$  is equal to 3 and  $n_1$  is 4, 5, 6 etcetera, then you get what is known as the Paschen series. These are the different series in atomic spectra and similarly, you will obtain the series for deuterium atom, the helium single ionized helium atom and the lithium atom.

(Refer Slide Time: 17:34)

The image shows a handwritten derivation of the Rydberg formula for hydrogen-like atoms. The equations are as follows:

$$E_{n_1} = -\frac{\mu Z^2 \alpha^2 c^2}{2 n_1^2} \quad T = \frac{E_n}{hc} = -\frac{\mu Z^2 \alpha^2 c^2}{2 n^2 hc}$$

$$E_{n_2} = -\frac{\mu Z^2 \alpha^2 c^2}{2 n_2^2} \quad R = \frac{\mu \alpha^2 c^2}{h}$$

$$n = n_1 \rightarrow n = n_2$$

$$\frac{hc}{\lambda} = E_{n_1} - E_{n_2} = \frac{\mu Z^2 \alpha^2 c^2}{2} \left[ \frac{1}{n_2^2} - \frac{1}{n_1^2} \right]$$

$$\lambda = \frac{2hc}{\mu Z^2 \alpha^2 c^2} \left[ \frac{1}{n_2^2} - \frac{1}{n_1^2} \right]^{-1}$$

Below the equations, the reduced mass  $\mu$  is defined as:

$$\mu = \frac{m_e m_N}{m_e + m_N}$$

For the transition  $n = 3 \rightarrow n = 2$ , the wavelength  $\lambda$  is calculated for Hydrogen (H) and Deuterium (D) with  $Z = 1$ :

$$\lambda = 6.5647 \times 10^{-5} \text{ cm (H)}$$

$$\lambda = 6.5629 \times 10^{-5} \text{ cm (D)}$$

The name "Urey 1932" is written at the bottom left, and an "NPTEL" logo is at the bottom center.

Now, from this we can calculate, if one makes a transition from  $n = 1$  to  $n = 2$ . So, let me write it down that  $E_{n=1}$  is equal to minus  $\mu z^2$ ,  $\alpha^2$ ,  $c^2$  by  $2 n^2$  and  $E_{n=2}$  is equal to minus  $\mu z^2$ ,  $\alpha^2$ ,  $c^2$  by  $2 n^2$ .

So, if I have a transition from  $n$  is equal to  $n = 1$  to  $n$  is equal to  $n = 2$ , so you must write down, so the frequency of the wave light emitted will be  $h \mu$  or  $h c$  by  $\lambda$  is equal to  $E_{n=1} - E_{n=2}$ . So, this will be minus sign, so this will be  $\mu z^2 \alpha^2 c^2$  by  $2$ ,  $1$  over  $n^2$  square, minus  $1$  over  $n^2$  square. So, the wave length of the emitted light will be  $c$  and these  $c$  will cancel out. So, you get  $2 h$  by  $\mu z^2 \alpha^2$  into  $1$  over  $n^2$  square minus  $1$  over  $n^2$  square raise to the power of minus  $1$ .

Now, if I consider two atoms, one is the deuterium atom and the other is the hydrogen atom. As I mentioned, the hydrogen atom consists of one proton and one electron and the deuterium atom consists of one proton and one neutron.

So for both the cases  $z$  is equal to  $1$  but since the mass of the nucleus is larger here. So the reduced mass is  $m_e m_N$  of the nucleus divided by  $m_e + m_N$ , so because mass of the nucleus is larger here, the reduced mass in the two problems will be slightly different. In fact, what was observed was that in one of the transitions, in  $n$  equal to  $3$  to  $n$  equal to  $2$  transition, which is in the Balmer series, I will leave it as an exercise for you to calculate; the wave length that is emitted was  $6.5647$ . This is the visible regions  $10$  to the

power of minus 5 centimeter and 6.5629 into 10 to the power of minus 5 centimeter, this is for the hydrogen atom and this is for the deuterium atom.

It was Urey, the chemist in 1932, who discovered the presence of another line, in the spectrum of hydrogen. They had similar lines as the hydrogen atom but they were slightly shifted. He measured that carefully and this was in the year 1932 when quantum mechanics was already discovered and he said that this is isotope hydrogen, and he calculated the reduced mass, and from which you can calculate the mass of the deuterium nucleus. Then he said that this must be due to an isotope of hydrogen.

So, it is through spectroscopy that the heavy water or heavy hydrogen was discovered. So, you have here for example, the Rydberg constant, you see the energy in spectroscopy is usually measured in centimeter inverse. So, we write this as a term value is equal to  $E_n$  by  $h c$ . If I divide by  $h c$ , you will get minus  $\mu z^2 \alpha^2 c^2$  by  $n^2$  square divided by  $h$ .

So, this the dimension of this is centimeter inverse, and this quantity is known as the Rydberg constant that is minus  $z^2 R$  divided by  $n^2$  square. So, where  $R$  is known as the Rydberg constant, which is equal to  $\mu \alpha^2 c^2$  by  $h$ .

(Refer Slide Time: 23:36)

$R = 109677.58 \text{ cm}^{-1}$  (for the hydrogen atom)  $z=1$   
 $109707.56 \text{ cm}^{-1}$  (for the deuterium atom)  $z=1$   
 $109722.40 \text{ cm}^{-1}$  (for the  $\text{He}^+$  - atom)  $z=2$   
 $109728.90 \text{ cm}^{-1}$  (for the  $\text{Li}^{++}$  - atom)  $z=3$

$V(\lambda) = -\frac{Z^2 e^2}{\lambda}$   
 $= -\frac{Z^2 q^2}{4\pi\epsilon_0}$

$\text{Li}^+$

NPTEL

Because of the slight difference in the reduced mass the value of the Rydberg constant is slightly different. For the Rydberg constant is 1096 you may write it down if you feel

like 109677.58 centimeter inverse for the hydrogen atom, 109707.56 centimeter inverse for the deuterium atom. Both of them are  $z$  is equal to 1. This is  $z$  is equal to 2 for the helium plus atom and this is doubly ionized lithium atom in which this is  $z$  is equal to 3.

Here for the example, for the helium plus atom you have two protons and two neutrons and because of two protons the nuclear helium atom consists of two electrons. If you take one electron out then you will have the helium plus atom.

Similarly, for 3 lithium 7 you have three protons and four neutrons. In this, one of the isotopes of three protons and so the mass number is seven, the atomic number is three. So, for the neutral lithium atom, you will have three electrons, if you take two of them, you ionize two of them, then you will obtain a single electron atom but,  $z$  is equal to 3. Since, the mass is much heavier now the reduced mass is slightly larger and which results in a slightly different value of the Rydberg constant.

So, we have now obtained the solution of the Schrödinger equation, and the Eigen values spectrum correspond to the single electron atom, in which the potential energy function is given by minus  $z e$  square by  $r$  in the CGS system of units, and in the MKS system of units all that I have to do is replace  $e$  square by  $q$  square by  $4 \pi \epsilon_0$  naught and that is it. And  $q$  is the charge of the electron in coulombs and  $z$  is the charge of the nucleus, so that completes the energy Eigen values spectrum of a one electron atom.

(Refer Slide Time: 26:36)

$$u(\rho) = \rho^{l+1} e^{-\rho/2} {}_1F_1(a, c, \rho)$$

$$R(\rho) = N \rho^l e^{-\rho/2} {}_1F_1(l+1-\lambda, 2l+2, \rho)$$

$$= N \rho^l e^{-\rho/2} {}_1F_1(l+1-n, 2l+2, \rho)$$

$$N = \frac{\gamma^{3/2}}{(2l+1)!} \left\{ \frac{(n+l)!}{2n(n-l-1)!} \right\}^{1/2}$$

$n=5, l=4$

$$R_{54}(\rho) = N \rho^4 e^{-\rho/2} {}_1F_1(0, 10, \rho)$$

$$\int_0^\infty |R_{n\ell}(\rho)|^2 \rho^2 d\rho = 1$$

$R(\rho) = \frac{u}{\rho}$

Now, we go back to the radial part of the Schrödinger equation and we have  $u$  of  $\rho$  as  $\rho$  to the power of  $l + 1$ ,  $e$  to the power of  $-\rho/2$ ,  $F_{l+1}$  of  $a c \rho$  and  $a$  was equal to  $l + 1 - \lambda$ ,  $c$  was equal to  $2(l + 1)$  and this is  $\rho$ . You may recall that  $R$  of  $r$  or  $R$  of  $\rho$  was equal to  $u$  of  $\rho$  by  $\rho$ .

So, the radial part of the wave function was equal to  $\rho$  to the, multiplied by a normalization constant  $N$ ,  $\rho$  to the power of  $l$ ,  $e$  to the power of  $-\rho/2$ . This is the rigorously correct wave function for the hydrogen atom. How would I determine?

These functions are so,  $\lambda$  was put equal to  $n$ , so let me write it down. This is the normalization constant,  $\rho$  to the power of  $l$ ,  $e^{-\rho/2}$ ,  $F_{l+1}$ ,  $l + 1 - n$ ,  $2(l + 1)$  into  $\rho$ , and the normalization constant is that is equal to that is very difficult to obtain, little cumbersome, I would not say,  $2(l + 1)!$  multiplied by  $n + 1$  factorial divided by  $2^n$  into  $n - l - 1$  factorial. The hypergeometric functions are much easier to handle than the associated Laguerre polynomials, which is motioned in most of the books.

Now, let us suppose that I want to find out, you give me any value of  $n$ , and any value of  $l$ , so let me find out for  $n$ .  $n$  is equal to 5 and  $l$  is equal to 4, so you can now see that  $l + 1 - n$ . so this function will be  $F_{l+1}$  will be 0,  $2(l + 1)$  will be 10 into  $\rho$ , but if  $a$  is 0 this is 1. I can immediately write down within a multiplicative constant  $R_{54}$  by of  $\rho$ , is equal to some normalization constant,  $\rho$  to the power of 4,  $e$  to the power of  $-\rho/2$ . If you do not want to remember this cumbersome formula, then you can immediately determine the normalization constant by saying that  $R_{nl}$  of  $r$  mod square, this is the normalization constant,  $r^2 dr$ , from 0 to infinity must be equal to 1.

(Refer Slide Time: 30:20)

$$\psi(r, \theta, \phi) = R_{nl}(r) Y_{lm}(\theta, \phi)$$

$$dx dy dz = r^2 dr \sin \theta d\theta d\phi$$

$$\int_0^\infty \int_0^\pi \int_0^{2\pi} |\psi|^2 r^2 dr \sin \theta d\theta d\phi = 1$$

$$\int_0^\pi \int_0^{2\pi} |Y_{lm}(\theta, \phi)|^2 \sin \theta d\theta d\phi = 1$$

$$R_{54}(r) = N r^4 e^{-r/2}$$

$$\rho = r$$

$$\int_0^\infty |R_{nl}(r)|^2 r^2 dr = 1$$

$$N^2 = \frac{1}{r^3} \int_0^\infty r^8 e^{-r} dr = 1$$

$$\int_0^\infty r^{10} e^{-r} dr = 1$$

$$N^2 = \frac{1}{10!} \Rightarrow N = \frac{1}{\sqrt{10!}}$$

So, you see the complete wave function,  $\psi$  of  $r$   $\theta$   $\phi$  is equal to  $R_{nl}$  of  $r$ ,  $Y_{lm}$  of  $\theta$   $\phi$ . This you must remember. This is normalized. So, in the cartesian system of coordinates the volume element is  $dx dy dz$ . In the spherical polar coordinates, the volume element is  $r^2 dr \sin \theta d\theta d\phi$ , so the normalization condition is  $|\psi|^2$  times this whole volume element  $r^2 dr \sin \theta d\theta d\phi$  triple integral  $r$  was from 0 to infinity,  $\theta$  goes from 0 to  $\pi$ , and  $\phi$  goes from 0 to  $2\pi$ , this must be equal to 1. This is the normalization condition.

So, if I take the  $r$  part outside and the  $\theta$  part outside, so the normalization condition for the spherical harmonic is this  $\theta$  going from 0 to  $\pi$ , and  $\phi$  going from 0 to  $2\pi$ , then modulus of  $Y_{lm}$   $\theta$   $\phi$  square  $\sin \theta d\theta d\phi$  is equal to 1. This is the normalization condition for the spherical harmonics and for the radial part, therefore, for the radial part you will have integral 0 to infinity  $R_{nl}^2$   $r^2 dr$ , actually they are all real,  $r^2 dr$  is equal to 1 this is  $r$  and not  $\rho$  (Refer Slide Time: 32:51).

So, we had here for example,  $R_{54}$  of  $r$ , I hope I have done it correctly, so  $R_{54}$  of  $r$  is equal to  $N \rho^4 e^{-\rho/2}$ . So,  $\rho$  is equal to  $\gamma r$ , so we can see if I multiply by  $\gamma^3$ , then I have a one over  $\gamma^3$   $N^2$ ,  $\rho^8 e^{-\rho}$ , this is  $R_{nl}$ ,  $e^{-\rho}$  and then  $\rho^8 d\rho$ , from 0 to infinity.

So, this is 0 to infinity, rho to the power of 10, e to the power of minus rho d rho, is equal to 1. So, this is 10 factorial, so N square is equal to gamma cubed into 10 factorial, or N will be gamma to the power of 3 by 2 square root of 10 factorial. So, if you want to do or if you want to calculate any radial part of the wave function then it is really very simple.

(Refer Slide Time: 34:46)

$$R_{nl}(r) = N \rho^L e^{-\rho/2} {}_1F_1(L+1-n, 2L+2, \rho)$$

$$R_{42}(r) \quad n=4; L=2. \quad a=-1$$

$${}_1F_1(-1, 6, \rho) = 1 + \frac{-1}{6} \frac{\rho}{1!} + 0$$

$$= \left(1 - \frac{\rho}{6}\right)$$

$$R_{42}(r) = N \rho^2 e^{-\rho/2} \left(1 - \frac{\rho}{6}\right)$$

Let me give you another example. So, as I have said  $R_{nl}(r)$  is equal to  $N \rho$  to the power of  $l$ ,  $e$  to the power of minus  $\rho$  by 2,  ${}_1F_1(l+1-n, 2l+2, \rho)$ . Now, let me calculate for  $R_{42}(r)$ , just an example. So,  $n$  is four and  $l$  is 2, so let me first calculate what is this function.

This is the hyper geometric function is  $l+1-n$ , that is  $2+1$  that is 3 minus 4 that is minus 1, and  $2l+2$  that is equal to  $c$  is equal to 4 plus 6 into  $\rho$ , and this is 1 plus  $a$  by  $c$ , that is minus 1 by 6, into  $\rho$  by factorial 1, then  $a$  is minus 1.

So,  $a$  into  $a+1$ , so that is 0. So, this will be just one minus  $\rho$  by 6. So,  $R_{42}(r)$  will be equal to  $n$ ,  $l$  is two, this is  $E$  to the power of minus  $\rho$  by 2 minus  $\rho$  by 6. Confluent hyper geometric equations function gives you very readily the complete radial part of the wave function, provided you, of course, you must be given the values of  $n$  and  $l$ .

So, this completes the analysis of the hydrogen like atom spectrum. What I would like to do or before that let me summarize.

(Refer Slide Time: 37:17)

Handwritten equations on a green chalkboard:

$$V(r) = -\frac{Ze^2}{r}$$

$$\nabla^2 \psi + \frac{2\mu}{\hbar^2} \left[ E + \frac{Ze^2}{r} \right] \psi(r, \theta, \phi) = 0$$

$$\psi(r, \theta, \phi) = R_{nl}(r) Y_{lm}(\theta, \phi)$$

$$R_{nl}(r) = N r^\rho e^{-\rho/2} {}_1F_1(\ell+1-2, 2\ell+2, \rho)$$

$$E = E_n = -\frac{Z^2 e^2 \alpha^2 \mu}{2n^2}$$

$E > 0$

NPTEL

Let me summarize therefore, you will have  $V$  of  $r$  for a minus  $z$  square by  $r$  and the wave function will be one describing the translational motion of the total hydrogen atom or hydrogen like atom. The total motion of the center of mass as a free particle and the internal motion, for that we have to solve in terms of the radial coordinate,  $2\mu$  by  $\hbar$  cross square,  $E$  minus  $V$  of  $r$ , that is plus  $z e$  square by  $r$ ,  $\psi$  of  $r$  theta phi and then  $\psi$  of  $r$  theta phi was equal to  $R_{nl}$  of  $r$ ,  $Y_{lm}$  of theta phi. These are the spherical harmonics and this is the radial part of the wave function, and the radial part of the wave function is  $R_{nl}$  of  $r$  is equal to  $n$  rho to the power of 1,  $e$  to the power of minus rho by 2,  $F_1(1, 1 + 1 - 2, 2 + 2 \text{ into } \rho)$ , and we have already discussed.

Finally, the energy Eigen values are  $E$  is equal to  $E_n$  minus  $z$  square,  $c$  square,  $\alpha$  square  $\mu$  by  $2n$  square. These are the energy eigen values of the hydrogen like atom problem and we discussed that that you can use this formula to calculate to obtain the spectra associated with the hydrogen like hydrogen atom, deuterium atom, simply ionized helium atom, doubly ionized lithium atom and so on.

There is one thing that I would like to mention that we have considered the negative energy states. Now, the positive energy states is if I have a proton sitting here, and an electron comes from very distance and get scattered. So, those are the  $E$  greater than 0 states. So, even in planetary motion, you can have a object, which comes near the sun

and gets scattered and then there is earth, which is bound to be sun, which is rotating in a orbit. So, even in the hydrogen atom, in both the cases we have inverse square law.

(Refer Slide Time: 40:33)

In quantum mechanics also, there are two types of solutions. One corresponds to  $E$  less than 0, so those are the bound state solution and for  $E$  greater than 0, those are the scattering state, for any problem, scattering solutions. Even in the neutron, proton problem, you have a bound state problem, in which the neutron and proton are held together and you find the discrete energy states.

On the other hand, you can have a neutron proton scattering problem, which is one of the most important problems in quantum mechanics, that you have a neutron beam coming in here, and getting scattered by the proton. So, this is known as the neutron proton scattering. So, those correspond to the continue solutions,  $E$  greater than 0.

In one dimensional quantum mechanics, you had remembered, that we had the potential well problem. Now, in this potential well problem, there are two types of solutions. Let us suppose 0 and  $V_0$ , for  $E$  lying between 0 and  $V_0$ , they are bound state solutions, where the particle is confined within the well, where your wave functions which are exponentially decaying here.

So, they are tightly confined here. They are localized and the energy Eigen values are discrete. So, these are known as the discrete bound states; **discrete bound states**, and then

we will have  $E$  greater than 0 solutions. These are the scattering state, and therefore will continue, all possible values of energy are allowed and therefore, you will have this and incident beam coming in, part of it is reflected and part of it is transmitted.

So, we will have two types of solutions, in the hydrogen atom problem or what we will be going to discuss is the neutron proton problem. We will just now confine ourselves to the negative energy solutions in which you have what are known as the bound states.

(Refer Slide Time: 43:18)

Example - Deuteron Problem

$\circ$  n     $\oplus$  p  
 $0 < r < \infty$

$V = \infty \quad r = b$

$\frac{d^2 u}{dr^2} + \frac{2\mu}{\hbar^2} \left[ E - V(r) - \frac{l(l+1)\hbar^2}{2\mu r^2} \right] u(r) = 0$

hard-core potential

$\frac{d^2 u}{dr^2} + \frac{2\mu}{\hbar^2} [V_0 - |E|] u(r) = 0 \quad b < r < a+b$   
 $V(r) = -V_0$

$\frac{d^2 u}{dr^2} - \frac{2\mu |E|}{\hbar^2} u(r) = 0 \quad r > a+b$

$\frac{d^2 u}{dr^2} - \kappa^2 u(r) = 0 \quad \kappa^2 \equiv \frac{2\mu |E|}{\hbar^2}$

$u(r) = C e^{-\kappa r} + D e^{+\kappa r}$

NPTEL

Now, let me just start and then we will continue with that in our next lecture. We considered the deuteron problem. This is the fundamental problem in nuclear physics. The deuteron problem in which you have a neutron and proton, now, scattering experiment suggest that because neutron is an uncharged particle, we have no interaction beyond a certain distance. So, there is a model, in which you have  $V$  is equal to infinity at  $r$  is equal to  $b$ , something like this, this is the potential as a function of  $r$ , so at  $r$  is equal to  $b$ , is an infinite potential and then it is minus  $V_0$  from  $r$  equal to  $b$  to  $a+b$ , and then it is 0 beyond this. This is known as the hardcore potential; hardcore potential, in which the neutron and the proton cannot be closer than the distance  $b$ .

So, let me write down the radial part of the Schrödinger equation. So,  $\frac{d^2 u}{dr^2} + \frac{2\mu}{\hbar^2} [E - V(r) - \frac{l(l+1)\hbar^2}{2\mu r^2}] u(r) = 0$ . I assume consider the  $l$  equal to 0 problem, just to make

life simple, and then you have, you must always remember  $r$  goes from 0 to infinity, not minus infinity to plus infinity.

We will consider once again the negative energy states of the problem and so  $E$  is negative and  $l$  is 0. This we consider as example two, the deuteron problem, so you have  $\frac{d^2 u}{dr^2} + 2\mu(V - E)u = 0$ .  $E$  is negative, so I write this down as  $V$  of  $r$  is equal to  $V_0$ , minus  $V_0$ , so  $V_0$  minus mod of  $E$ . I hope you understand.  $u$  of  $r$  is equal to 0, this is for  $r$  less than  $a$  plus  $b$ , less than  $b$ . In this region  $V$  of  $r$  is assumed to be minus  $V_0$ , minus  $V_0$ .

For  $r$  greater than  $a$  plus  $b$ , you will have  $V$  of  $r$  is 0, this term is 0, but  $E$  is assumed to be negative. These are the bound state problems, so  $\frac{d^2 u}{dr^2} - 2\mu|E|u = 0$ . So, this is for  $r$  greater than  $a$  plus  $b$ . So, in the region  $r$  greater than  $a$  plus  $b$ , I write this as  $\frac{d^2 u}{dr^2} - \kappa^2 u = 0$ , where  $\kappa^2$  is defined to be equal to  $2\mu|E|$  by  $\hbar^2$ 's square.

(Refer Slide Time: 48:19)

$u(r) = ce^{-\kappa r} + De^{\kappa r}$   
 Exponentially Blow up  
 $D = 0$   
 $r > a+b$   
 $u(r) = Ce^{-\kappa r}$   
 $b < r < a+b$   
 $\frac{d^2 u}{dr^2} + k^2 u(r) = 0$   
 $k^2 = \frac{2\mu}{\hbar^2} [V_0 - |E|]$   
 $u(r) = A \sin k(r-b) + B \cos k(r-b)$   
 $r=b \quad u=0$   
 $u(r=b)=0$   
 $0 = B$   
 $u(r) = A \sin k(r-b)$

So, as we all know, this has two particular solutions. So, the solution may be  $u$  of  $r$  will be say  $ce^{-\kappa r}$  plus  $De^{\kappa r}$ . This will exponentially blow up and therefore, the wave function will not be normalizable. So, you must choose  $D$  is equal to 0, so in the region  $r$  greater than  $a$  plus  $b$ , the wave function will be  $u$  of  $r$  is equal to  $Ce^{-\kappa r}$ .

In the region of b, for r lying between a plus b and b, this we write as  $\frac{d^2 u}{dr^2} + k^2 u = 0$ , so where  $k^2$  is equal to  $2\mu(E - V)$ .

The solutions are very simple;  $A \sin k r$ , so I write this as  $r - b + b \cos$  of  $k r - kb$ . Just, I have introduced this B for the sake of simplicity. Now, at  $r$  is equal to  $b$  there is an infinite potential, so the wave function has to go to 0, because the inter particle distance cannot be less than  $b$  and that is what this potential physically implies. This is known as the hardcore potential where the neutron and the proton **cannot...** This is one of the models and no one really knows the exact potential energy distribution between the neutron and the proton.

This is a simple model which is quite accurate that for distances between the neutron and the proton cannot be less than  $b$ , so at  $r$  equal to  $b$ , the wave function must be 0. So, at  $r$  equal to  $b$  the wave function is 0 so  $u$  at  $r$  equal to  $b$  must be 0. So, if I put  $r$  equal to  $b$ , this term goes 0. So, 0 is equal to, this is  $\cos$  of 0 so that  $b \cos$  of 0 is one, so this term  $b$  is 0.

(Refer Slide Time: 51:56)

$$\begin{aligned}
 &b < r < a+b & u(r) &= A \sin k(r-b) \\
 &r > a+b & u(r) &= C e^{-\kappa r} \\
 &\text{Continuity of } u(r) \text{ at } r=b+a & & \\
 &A \sin ka = C e^{-\kappa(a+b)} \\
 &kA \cos ka = -\kappa C e^{-\kappa(a+b)} \\
 &-\kappa a \cot ka = \kappa a \\
 &-\xi \cot \xi = \eta \\
 &\xi^2 = k^2 a^2 \\
 &= \frac{2\mu}{\hbar^2} [V_0 - |E|] a^2 ; \eta^2 = \kappa^2 a^2 = \frac{2\mu |E| a^2}{\hbar^2}
 \end{aligned}$$

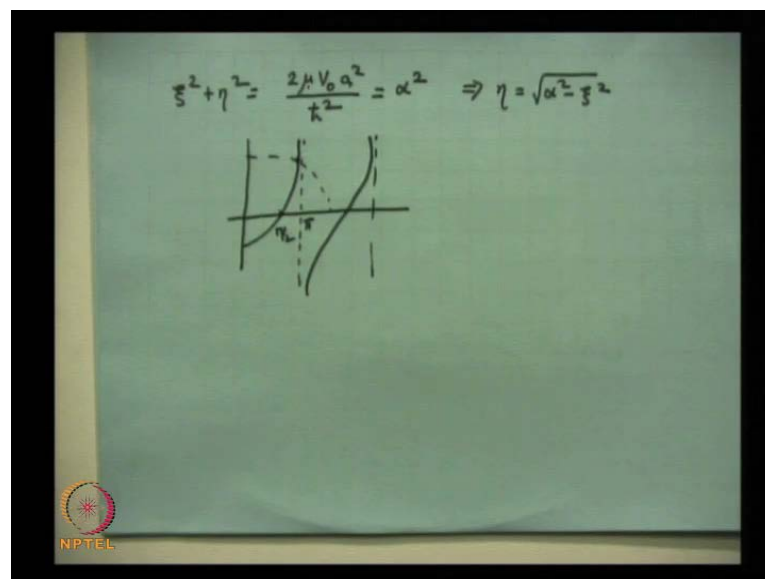

You had  $u$  of  $r$  is equal to  $A \sin k$  of  $r$  minus  $b$ . Therefore, we will have for  $r$  less than  $a$  plus  $b$ , less than  $b$ ,  $u$  of  $r$  is a  $\sin k r$  minus  $b$ , for  $r$  greater than  $a$  plus  $b$ ,  $u$  of  $r$  will be  $c$  into  $e$  to the power of minus  $\kappa r$ .

We must have the wave continuity of the wave function of  $u$  of  $r$  at  $r$  is equal to  $b$ , will give me  $a$   $r$  is equal to  $b$  plus  $a$ , continuity at  $r$  equal to  $a$  plus  $b$  will give me  $A \sin k a$ , is equal to  $c \sin e$  to the power of minus  $kappa$   $a$  plus  $b$ .

Similarly, if I take the derivative continuity of  $u$  prime of  $r$ , so this will be  $k a \cos k r$  minus  $b$  and at  $r$  equal to  $a$  plus  $b$ , it will be  $\cos k a$  minus  $c \kappa e$  to the power of minus  $kappa$   $a$  plus  $b$ . so, if I divide this equation this equation by this equation, I will get minus  $k a \cot k a$  is equal to  $kappa$ . So, if I multiply both sides by  $a$ , so I will get something like this.

So, this is an equation which is similar to what we are encountered earlier. So, minus  $\psi \cot \psi$  is equal to  $\eta$ , where  $\xi^2$  is equal to  $k^2 a^2$ , and this is equal to  $2 \mu V_0 a^2$  by  $\hbar^2$  and  $\eta^2$  is equal to  $k^2 b^2$  minus  $k^2 a^2$ , and that is equal to  $2 \mu V_0 b^2$  by  $\hbar^2$  minus  $2 \mu V_0 a^2$  by  $\hbar^2$  and if I add these two equations then I will get...

(Refer Slide Time: 54:55)

The image shows a green chalkboard with handwritten mathematical equations and a graph. At the top, the equation  $\xi^2 + \eta^2 = \frac{2\mu V_0 a^2}{\hbar^2} = \alpha^2 \Rightarrow \eta = \sqrt{\alpha^2 - \xi^2}$  is written. Below the equation is a graph with a horizontal axis labeled  $\xi$  and a vertical axis labeled  $\eta$ . A quarter-circle arc is drawn in the first quadrant, starting from the  $\eta$ -axis and ending at the  $\xi$ -axis. A point on the arc is labeled with the Greek letter  $\eta$ . The NPTEL logo is visible in the bottom left corner of the chalkboard.

If I add these two equations  $\xi^2$  plus  $\eta^2$ , then you can see  $\eta^2$  cancels out, so you get  $2 \mu V_0 a^2$  by  $\hbar^2$ . This I put equal to  $\alpha^2$  and for a given potential, for a given reduced mass, for a given radius, and of course, Planck's constant is a constant, so therefore, this gives me that  $\eta$  is equal to under root of  $\alpha^2$  minus  $\xi^2$ . Therefore, this term will be just the similar thing that we had experience in our one dimensional case.

So, for a given value of  $\alpha$ , we have to solve this transcendental equation and obtain the discrete eigen value, so minus  $\xi \cot \xi$ , we have something like this. This is a  $\pi$  that it will become infinite, and this is  $\pi$  by 2, and then you will have something like this, and the right hand side will be the quadrant of a circle, and the points of intersection, will give me the eigen values.

We will specifically consider a profile which closely corresponds to the deuteron problem and then we will solve this equation and obtain the Eigen values of the problem. Thank you.
