**Dirac's Bra and Ket Algebra The Linear Harmonic Oscillator**

In the previous lecture, we had developed the algebra, relating to the Bra and Ket notation and we had also defined consider linear operators and define the adjoint of a linear operator.

(Refer Slide Time: 01:01)

$$\begin{aligned} \bar{\alpha} &= \alpha \\ \langle A | \bar{\alpha} | A \rangle &= \langle A | \alpha | A \rangle \\ \alpha | A_0 \rangle &= a_n | A_n \rangle \\ \alpha | A_n \rangle &= 0 \\ \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \\ \bar{\alpha} &= \alpha \quad a_n \text{ is necessarily real} \end{aligned}$$

For example, if we consider the linear operator alpha, then its adjoint is denoted by alpha bar and if alpha bar is equal to alpha. That means that alpha bar ket A bra A is equal to bra A alpha A and if this is valid, then alpha bar is equal to alpha, and we say that the operator is a real operator or a self adjoint operator.

Then we said that if I consider the eigen value equation that is alpha ket A n is equal to A n ket A n. This is a number, alpha operating on a ket, which is by definition in non null

ket, otherwise it is a trivial solution. So, if  $\alpha$  operating on a ket, gives a multiple of the same ket, then we say that  $a_n$  is an eigen value of the operator  $\alpha$  and ket  $A_n$  is the corresponding eigen ket.

We can have a situation that  $\alpha A_n$  is a null ket, is equal to 0. Then if  $\alpha$  is not a null operator and if ket  $A_n$  is a not a null ket, then this is a perfectly valid equation, and 0 is an eigen value. I gave an example that if I have an, say 3 by 3 matrix, say  $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}$ , the eigen values are (1 0 and minus 1). I just consider a simple matrix, then this operating on  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$ , will be  $\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$ . So, this is a well behaved; this is an eigen ket of the this operator, belonging to the eigen value 0.

We said that when if  $\bar{\alpha}$  is  $\alpha$ , then  $a_n$  is necessarily real. Now, Dirac argues in his famous book, the reference to which I have given in my previous lecture, and he argues like this, all observables, anything that we can measure, like the position momentum, energy, angular momentum or anything, they are to be represented by real linear operators” and when we make a measurement a precise measurement of that observable, then we will get one of the eigen values, and then since we will get only a real number, all eigen values must necessarily be real, and Dirac further argues that it is an axiom that all observables must be represented by a real linear operator.

So, I repeat Dirac writes in his book, that any observable like the x coordinate, the position or the y component of the momentum or the z component of the angular momentum or the energy or something like that, any quantity that can be measured is represented by a real operator or a self adjoint operator. When you make a measurement of that observable, you get one of the eigen values; we will illustrate this by solving the harmonic oscillator problem.

(Refer Slide Time: 06:19)

$$H|H'\rangle = H'|H'\rangle$$

$$[x, p] = xp - px = i\hbar \quad \hbar = \frac{h}{2\pi}$$

$$a = \frac{\mu\omega x + ip}{\sqrt{2\mu\hbar\omega}}; \quad \bar{a} = \frac{\mu\omega x - ip}{\sqrt{2\mu\hbar\omega}}$$

$$\hbar\omega a \bar{a} = \frac{1}{2\mu} [\mu^2\omega^2 x^2 + p^2 - i\mu\omega(xp - px)]$$

Let me consider the linear harmonic oscillator problem. We had solved the Schrodinger equation for that linear harmonic oscillator problem, in which the hamiltonian, the operator representing the total energy, is given by  $p^2 / 2\mu$ , plus  $\frac{1}{2}\mu\omega^2 x^2$ , where  $p$  is actually the  $x$  component of the momentums, and  $x$  is the position coordinate. Of course,  $\mu$  is the mass,  $\omega$  is the frequency. So, these are constants, now  $\hbar$  is of course, a constant. This is the kinetic energy and this is the potential energy.

Dirac says, since  $x$  and  $p$ , actually it is  $p x$ , and since it is a one-dimensional problem, we replaced by  $p$ , and he says that since  $x$  and  $p$  can be measured, these are real operators. That is  $\bar{x}$  by definition is  $x$ ,  $\bar{y}$  is  $y$  and  $\bar{p}$  that is  $\bar{p} x$  is  $p$  and of course,  $\bar{H}$  is equal to  $H$ .

What we would like to do is that we would like to solve this eigen value equation.  $H$ , he writes it in this form,  $H|H'\rangle = H'|H'\rangle$  (Refer Slide Time: 08:06). Our objective for the next 1 hour or so will be to solve this eigen value equation. Now, the only thing that he assumes that we had derived sometime back is the commutation relation. You recall that we had said that that  $x, p$ , this is known as the commutator of  $x$  and  $p$ . This was equal to  $xp - px$ , the 2 operators do not commute, and this is equal to  $i\hbar$ , where  $\hbar$  is the Planck's constant divided by  $2\pi$ .

So, we will just assume this, and use the Bra-Ket algebra to solve this equation, and this procedure is due to Dirac himself, and this really a very elegant procedure. Dirac defines two operators. These are not real operators, he defines it as,  $a$  equal to  $\frac{1}{2} \mu \omega x + i p$ . This is a constant,  $\omega$  is a constant,  $x$  is of course, the  $x$  coordinate, plus  $i p$ , where  $i$  is square root of minus 1, divided by under root of  $2 \mu h$  cross  $\omega$ . Then the adjoint of these operator is  $a^\dagger$ , and is equal to  $\frac{1}{2} \mu \omega x - i p$ ,  $i$  will be replaced by minus  $i$ ,  $p$  bar is  $p$ ,  $x$  bar is  $x$ , and these are of course, numbers, real numbers divided by  $2 \mu h$  cross  $\omega$ .

He defines this two operators and the recalculates  $h$  cross  $\omega$   $a^\dagger a$ . So, you have, if you multiply this by this, you will get  $2 \mu h$  cross  $\omega$  is the denominator. The  $h$  cross  $\omega$  will cancel out, so you will get  $1$  over  $2 \mu$  of  $\mu \omega x$  plus  $i p$  multiplied by  $\mu \omega x$  minus  $i p$ . Now, it is something like a plus  $i b$  and a minus  $i b$ . So, do not be in a hurry to write this as a square minus  $b$  square, because  $x p$  is not equal to  $p x$ . So, one has to be little careful, so let us do this carefully.

So, we will have  $1$  over  $2 \mu$ , the first term will be  $\mu^2 \omega^2 x^2$ , and this  $i$  times  $i$  is minus  $1$ , and into minus  $1$  is plus  $1$ , so  $p^2$ . And if I take minus  $i \mu \omega$  outside, so it will be  $x p$  minus  $p x$ . This is the crucial part of the calculation. Sorry, this is  $p^2$ , so  $i p$  times minus  $i p$  is  $p^2$ .

(Refer Slide Time: 12:32)

$$\begin{aligned} \hbar \omega \quad a^\dagger &= H - \frac{1}{2} \omega \cdot i k = H + \frac{1}{2} \hbar \omega \\ \hbar \omega \quad a &= \frac{\hbar \omega}{2 \mu \hbar \omega} [\mu \omega x - i p] [\mu \omega x + i p] \\ \hbar \omega \quad a^\dagger a &= H a + \frac{1}{2} \hbar \omega a \quad x a \\ \hbar \omega \quad a a^\dagger &= a H - \frac{1}{2} \hbar \omega a \\ H a + \frac{1}{2} \hbar \omega a &= a H - \frac{1}{2} \hbar \omega a \\ H a |H'\rangle &= a |H'\rangle + \hbar \omega a |H'\rangle \\ H |H'\rangle &= H' |H'\rangle \end{aligned}$$

$H |H'\rangle = H' |H'\rangle$

$H |H'\rangle = H' |H'\rangle$

So, we will have if you write this, so you will have  $\hbar \omega$ . Please, leave some space here. Here,  $\bar{a}$ , this is  $p^2$  by  $2\mu$  plus  $\frac{1}{2}\mu\omega^2 x^2$ . So, that is my  $H$  and this is the  $H$ , the Hamilton (Refer Slide Time: 13:00), which is  $p^2$  by  $2\mu$  plus  $\frac{1}{2}\mu\omega^2 x^2$ . So, this is  $H$  minus  $i$  by  $2$ , the  $\mu$  and  $\mu$  cancel out,  $\omega$  and  $x$   $p$  minus  $p$   $x$  is  $i\hbar$  cross. So, this is  $i\hbar$  cross. So,  $i$  times  $i$  is minus 1, minus and minus is plus 1. So, we will obtain this is equal to  $H$  plus half  $\hbar$  cross  $\omega$ .

Similarly, I can write down for  $\hbar \omega$ ,  $\bar{a}$  and this is equal to again  $\hbar \omega$  divided by  $2\mu$   $\hbar \omega$ . So,  $\bar{a}$  will be  $\mu\omega$ ,  $x$  minus  $i$   $p$  multiplied by  $\mu\omega$   $x$  plus  $i$   $p$ . Everything will remain the same, except that instead of  $x$   $p$  minus  $p$   $x$ , it would be  $p$   $x$  minus  $i$   $p$  (Refer Slide Time: 14:29). So, here there will be a change in sign. So,  $\mu^2\omega^2 x^2$  plus  $p^2$ , will remain the same, except since this is in reverse order, so this will change sign. So, I leave that as an exercise. I hope you can work this out yourself.

We will get two equations. One is the top equation, let me rewrite it. So,  $\hbar \omega$ ,  $\bar{a}$  is equal to  $H$  plus half  $\hbar \omega$  and that is it. The second one will be  $\hbar \omega$ ,  $\bar{a}$ , leave some space, is equal to  $H$  minus half  $\hbar \omega$ .

What I do is that I multiply this equation, on the right by  $\bar{a}$ , so I get  $\bar{a}$  here. I get  $\bar{a}$  here and  $\bar{a}$  here. Here, you pre multiply by  $\bar{a}$ , so you get,  $\bar{a}H$ . So, the left hand sides are equal and you therefore, get  $\bar{a}H$  plus half  $\hbar \omega \bar{a}$ , is equal to  $\bar{a}H$  minus half  $\hbar \omega \bar{a}$ . So, I take this to that side, so you will get  $\bar{a}H$ , is equal to  $\bar{a}H$  minus  $\hbar \omega \bar{a}$ . Operate this on the eigen ket of  $H$  prime. So,  $\bar{a}$  operating on  $H$  prime,  $H$  operating on  $H$  prime, and this operating on  $H$  prime.

We know that  $H$  prime ket  $H$  prime is an eigen ket.  $H$  ket  $H$  prime is an eigen ket, so this is just a number, ket  $H$  prime is an eigen ket of the operator  $H$ , belonging to the eigen value  $H$ . This is what we had started out that we want to solve this eigen value equation. So, we say that let ket  $H$  prime be an eigen ket of the operator  $H$  with  $H$  prime as the corresponding eigen value.

(Refer Slide Time: 18:15)

$$\begin{aligned}
 H|P\rangle &= (H' - \hbar\omega)|P\rangle; |P\rangle \equiv a|H'\rangle \\
 H a|P\rangle &= a H|P\rangle - \hbar\omega a|P\rangle \\
 H|Q\rangle &= (H' - \hbar\omega)|Q\rangle - \hbar\omega|Q\rangle \\
 H|Q\rangle &= (H' - 2\hbar\omega)|Q\rangle \quad |Q\rangle \equiv a|P\rangle \\
 |P\rangle &= a|H'\rangle \\
 \langle P| &= \langle H'|\bar{a} \\
 \hbar\omega \langle P|P\rangle &= \langle H'|\hbar\omega \bar{a} a|H'\rangle \\
 &\geq 0 = \langle H'|H - \frac{1}{2}\hbar\omega|H'\rangle \\
 &= 0 \frac{1}{2}\hbar\omega \langle P|P\rangle = (H' - \frac{1}{2}\hbar\omega) \langle H'|H'\rangle \geq 0 \\
 &\quad H|H'\rangle = H'|H'\rangle \\
 &\quad H' \geq \frac{1}{2}\hbar\omega \\
 &\quad H' = \frac{1}{2}\hbar\omega \\
 &\quad |P\rangle = 0
 \end{aligned}$$

So, we obtain from here, if I rewrite this slightly, so we get H operating on a H prime. That is let me write down as P. This will be a H operating on H prime, will be H prime. H prime is a number, which I can put outside, so H prime and then minus h cross omega times ket P, where ket P is defined to be equal to a ket H prime. This is an extremely important equation (Refer Slide Time: 19:06) and it says that if ket H prime is an eigen ket of the operator H, then ket P, which is equal to a ket H prime, is also an eigen ket of the operator H, belonging to the eigen value H prime minus h cross omega, provided this is not a null ket, because if it is a null ket it is a trivial solution.

So, I repeat and you must understand this that if ket H prime, of course, this is not a null ket; ket H prime is an eigen ket of the operator H belonging to the eigen value H prime, then ket P, which is equal to a ket H prime, is also an eigen ket of this same operator H, corresponding to the value eigen value H prime minus h cross omega ket P.

Now, I can proceed further. You remember that we had the relation that H a was equal to a H minus h cross omega a. We had derived this relation. Now, instead of ket H prime, I now operate this on ket P, and this on ket P, and this on ket P, and we will obtain H ket P is equal to H prime minus h cross omega. So, this will be equal to H prime minus h cross omega a ket P. Let me write this as ket Q. So, this is H operating on ket Q. This will be equal to minus h cross omega ket Q, where ket Q, let me write it carefully, ket Q is

defined to be equal to a ket  $P$ , and so this becomes  $H Q$  is equal to  $H$  prime minus  $2 \hbar \omega$  ket  $Q$ .

Thus, if ket  $P$  is a non null ket and is an eigen ket of the operator  $H$ , then ket  $Q$ , which is defined as a ket  $P$  is also an eigen ket of the operator  $H$ , belonging to the eigen value  $H$  prime minus  $2 \hbar \omega$ .

Therefore, we see that  $H$  prime is an eigen ket, if the corresponding eigen value is eigen ket is  $H$  prime. Then  $H$  prime minus  $\hbar \omega$ , the eigen ket is a ket  $H$  prime and  $H$  prime minus  $2 \hbar \omega$ . Then this will be a, a ket  $H$  prime and similarly, you can proceed indefinitely, provided any one of them a, a, a,  $H$ ; provided any one of them does not become a null ket.

Now, let me do a little more algebra. See the beauty of the algebra. Let me write down ket  $P$  is equal to a ket  $H$  prime, therefore, bra  $P$  is equal to  $H$  prime, a bar. So, I write this down as bra  $P$  ket  $P$ , a scalar product. So, let me multiply this by  $\hbar \omega$ . So, we get  $H$  prime  $\hbar \omega$ , a bar, a  $H$  prime.

Now, if you look up your notes, then we had derived **H sorry** a bar a,  $\hbar \omega$  a bar a (Refer Slide Time: 24:16) was equal to  $H$  minus half  $\hbar \omega$ , so we had derived this and this is equal to  $H$  prime  $H$  minus half  $\hbar \omega$ . So, you see this is just a number, so I can take it out.  $H$  operating on  $H$  prime is a multiple of  $H$  prime, so this becomes  $H$  prime minus half  $\hbar \omega$  bra  $H$  prime ket  $H$  prime.

Now, you see this is of course a positive number, and see the beauty of the logic. This is of course a positive definite. This is greater than or equal to 0. This is greater than or equal to 0 if and only if  $P$  is a null ket. So, this tells us that  $H$  prime must be greater than or equal to half  $\hbar \omega$  and  $H$  prime is equal to half  $\hbar \omega$ , then this will become 0, then ket  $P$  must be a null ket.

(Refer Slide Time: 26:17)

$$\hbar\omega \langle P|P\rangle = (H' - \frac{1}{2}\hbar\omega) \langle H'|H'\rangle \quad (1)$$

$$\geq 0 \quad \langle H'|H'\rangle > 0 \quad H|H'\rangle = H'|H'\rangle$$

$$= 0 \text{ iff } |P\rangle = 0$$

Eq. (1) tells us that

$$H' \geq \frac{1}{2}\hbar\omega$$

$$H' = \frac{1}{2}\hbar\omega \text{ iff } \langle H'|H'\rangle = 0$$

$$\frac{1}{2}\hbar\omega, \frac{3}{2}\hbar\omega, \frac{5}{2}\hbar\omega, \dots$$

$$n=0 \quad (n+\frac{1}{2})\hbar\omega \quad n=1 \quad n=2 \dots$$

Let me repeat this and it is a very important argument. I have here  $\hbar\omega$  cross  $P$ ,  $P$  is equal to  $H$  prime minus half  $\hbar\omega$  bra  $H$  prime ket  $H$  prime. Now,  $H$  operating on  $H$  prime is  $H$  prime and this is of course, a non null ket. Otherwise, it is a trivial solution. So, we assume that ket  $H$  prime is an eigen ket of the operator  $H$ , and the corresponding eigen value is  $H$  prime. So, this says that this is positive, definitely positive definite.

This is greater than or equal to 0 and equal to 0, if and only if ket  $P$  is a null ket. Therefore, this equation tells us, this equation one tells us (Refer Slide Time: 27:16) that  $H$  prime must be equal to or greater than, must always be greater than or equal to  $H$ , it can be  $H$  prime is equal to half  $\hbar\omega$  if and only if a ket  $H$  prime is a null ket.

We see (Refer Slide Time: 27:53) that we just now obtained that if  $H$  prime is an eigen ket, the eigen value, then  $H$  prime minus  $\hbar\omega$ , then  $H$  prime minus 2  $\hbar\omega$ ,  $H$  prime minus 3  $\hbar\omega$ ; this cannot go on indefinitely. This cannot go on indefinitely, because then it will violate this inequality (Refer Slide Time: 28:18) and therefore, at some stage, it must terminate and it can terminate only, if a ket  $H$  prime is a null ket. That can happen only at half  $\hbar\omega$  and this is absolutely beautiful.

So you see that you will have eigen values, as half  $\hbar\omega$ , 3 half  $\hbar\omega$  and 5 halves  $\hbar\omega$  and so on. So, if I write this as  $n$  plus half  $\hbar\omega$ ,

then  $n$  is 0 here,  $n$  is 1 here,  $n$  is 2 here, and if I write the corresponding kets as ket 0, the eigen kets, ket 1, ket 2.

(Refer Slide Time: 29:29)

Handwritten equations on a whiteboard:

$$H|0\rangle = \frac{1}{2}\hbar\omega|0\rangle$$

$$H|1\rangle = \frac{3}{2}\hbar\omega|1\rangle$$

$$H|2\rangle = \frac{5}{2}\hbar\omega|2\rangle \dots$$

The equation  $a|0\rangle = 0$  is boxed.

$$H' \geq \frac{1}{2}\hbar\omega$$

$$\& H' = \frac{1}{2}\hbar\omega \iff a|H'\rangle = 0$$

An NPTEL logo is visible in the bottom left corner of the whiteboard image.

That means what I am trying to say is that  $H$  ket 0 is equal to half  $h$  cross  $\omega$  ket 0.  $H$  ket 1 is equal to 3 by 2  $h$  cross  $\omega$  ket 1;  $H$  ket 2 is equal to 5 by 2  $h$  cross  $\omega$  ket 2 and so on. We will show that it has to go indefinitely and that I have not yet proved.

Then there cannot be an eigen value minus half  $h$  cross, for that to happen, we must have a ket 0 must be a null ket. So, we said, I go back that if I showed that  $H$  prime is always or greater than or equal to half  $h$  cross  $\omega$ . We first prove that and  $H$  prime is equal to half  $h$  cross  $\omega$ , if and only if, a ket  $H$  prime is a null ket. So, from half we can go to minus half, but that is not possible and that is not possible if a ket 0 is a null ket.

(Refer Slide Time: 31:17)

The whiteboard contains the following handwritten equations:

$$\begin{aligned} \hbar\omega \bar{a}a\bar{a} &= \bar{a}H + \frac{1}{2}\hbar\omega \bar{a} \\ \hbar\omega \bar{a}a\bar{a} &= H\bar{a} - \frac{1}{2}\hbar\omega \bar{a} \\ \bar{a}H + \frac{1}{2}\hbar\omega \bar{a} &= H\bar{a} - \frac{1}{2}\hbar\omega \bar{a} \\ \bar{a}H'|\mathcal{H}'\rangle + \hbar\omega \bar{a}|\mathcal{H}'\rangle &= H\bar{a}|\mathcal{H}'\rangle \\ (H' + \hbar\omega)\bar{a}|\mathcal{H}'\rangle &= H\bar{a}|\mathcal{H}'\rangle \end{aligned}$$

On the right side of the whiteboard, there is a note:  $H|\mathcal{H}'\rangle = H'|\mathcal{H}'\rangle$ .

$$\begin{aligned} H|\mathcal{R}\rangle &= (H' + \hbar\omega)|\mathcal{R}\rangle; |\mathcal{R}\rangle = \bar{a}|\mathcal{H}'\rangle \\ H|\mathcal{S}\rangle &= (H' + 2\hbar\omega)|\mathcal{S}\rangle \end{aligned}$$

Below the equations, there are three energy levels listed vertically:  $H'$ ,  $H' + \hbar\omega$ , and  $H' + 2\hbar\omega$ .

Let me go through this algebra once again little differently. So, we had obtained  $\hbar\omega \bar{a}a\bar{a} = \bar{a}H + \frac{1}{2}\hbar\omega \bar{a}$ ,  $\hbar\omega \bar{a}a\bar{a} = H\bar{a} - \frac{1}{2}\hbar\omega \bar{a}$ . Then you have  $\hbar\omega \bar{a}a\bar{a} = \bar{a}H + \frac{1}{2}\hbar\omega \bar{a}$  is equal to  $H\bar{a} - \frac{1}{2}\hbar\omega \bar{a}$ . Now, what we did was that in order to make the left hand side equal, I multiplied  $\bar{a}$  here and  $a$  on the left here,  $\bar{a}$  on the right here and  $a$  on the left here, so then it became left hand side became equal.

What we will do now is we could have also multiplied on the left by  $\bar{a}$  and on the right by  $\bar{a}$ . So, if I multiply this on the left by  $\bar{a}$ , then this is  $\bar{a}H + \frac{1}{2}\hbar\omega \bar{a}$ . This is of course a number, so it does not matter where I write, and on the right by  $\bar{a}$ ; it becomes  $H\bar{a} - \frac{1}{2}\hbar\omega \bar{a}$ . If I add this, so therefore, the left hand sides are equal. So, I get  $\bar{a}H + \frac{1}{2}\hbar\omega \bar{a} = H\bar{a} - \frac{1}{2}\hbar\omega \bar{a}$ .

So, what I do is I take this to this side, so you get  $\bar{a}H$ . Leave some space here, so plus  $\hbar\omega \bar{a}$ , half plus half is 1, leave some space here, this is equal to  $H\bar{a}$ . Now, what you do is that you operate this on ket  $|\mathcal{H}'\rangle$ , which is an eigen ket of the operator  $H$ . So, if you recall  $H|\mathcal{H}'\rangle = H'|\mathcal{H}'\rangle$ .

You can see  $H$  operating on  $|\mathcal{H}'\rangle$  is  $|\mathcal{H}'\rangle$  and this becomes a multiple. Then I can shift it here, because it is just a number. So, my left hand side becomes  $(H' + \hbar\omega)|\mathcal{H}'\rangle$ . This is equal to the same. So, let me turn the sides. So,

you get H, say ket R, is equal to H prime plus h cross omega ket R, where ket R is equal to a bar H prime. So, we have that.

Please listen to the logic of the argument; if ket H prime is an eigen ket of the operator H then ket R, which is equal to a bar ket H prime is also an eigen ket of the operator H. Now, belonging to an eigen value H prime plus h cross omega. Similarly, I can then again do the same kind of algebra, instead of operating this by H ket H prime, I will this by ket R, and I will obtain H ket S is equal to H prime plus h cross omega plus h cross omega. So, plus 2 h cross omega ket S. So, this will be again an eigen ket eigen value equation provided ket S is not an eigen, not a null ket.

If H prime is an eigen value then H prime plus h cross omega is also an eigen value, H prime plus 2 h cross omega, provided at any stage we do not get a null ket, then it becomes a trivial solution. But I will just now show it can never become a null ket and that the proof is as follows.

(Refer Slide Time: 36:33)

Handwritten mathematical derivation on a whiteboard:

$$|R\rangle = \bar{a} |H'\rangle$$

$$\langle R| = \langle H'| a$$

$$\hbar\omega \langle R|R\rangle = \langle H'| \underbrace{\hbar\omega a \bar{a}}_{H + \frac{1}{2}\hbar\omega} |H'\rangle$$

$$\text{If } |R\rangle \neq 0 \quad = (H' + \frac{1}{2}\hbar\omega) \underbrace{\langle H'|H'\rangle}_{>0}$$

then  $H' = -\frac{1}{2}\hbar\omega \times$

That if ket are is equal to a bar ket H prime, then bra R will be equal to bra H prime, a bar bar, which is a. So, if I write bra R ket R and if I multiply this by h cross omega, then I will get H prime a a bar sorry sorry I'm sorry h cross omega, a, a bar, and this was equal to, if you recollect, this was equal to H plus half h cross omega.

So H operating, if I let me just check this with my... yes this is correct, this is correct you will have that H operating on H prime is H prime, and this is just a number, so this becomes H prime plus half h cross omega. Now, this is always greater than 0 and if this becomes a null ket; if this is 0, then H prime becomes equal to minus half h cross omega. But, this violates the inequality that we had derived sometime back, which says that H prime must be greater than or equal to half h cross omega (Refer Slide Time: 38:34).

We had derived that H prime can at least the half h cross omega and that cannot be greater than that. But, here it says that if ket R is a null ket, then H prime must be equal to this. But, this is impossible, so ket R can never be a null ket. So, if ket are is never a null ket and if H prime is an eigen value.

(Refer Slide Time: 39:18)

Handwritten mathematical derivation on a whiteboard:

$$\begin{aligned} \omega \bar{a} a \bar{a} &= \bar{a} H + \frac{1}{2} \hbar \omega \bar{a} \\ \omega \bar{a} a \bar{a} &= H \bar{a} - \frac{1}{2} \hbar \omega \bar{a} \\ \bar{a} H + \frac{1}{2} \hbar \omega \bar{a} &= H \bar{a} - \frac{1}{2} \hbar \omega \bar{a} \end{aligned}$$

From the third equation, an arrow points to the right-hand side, leading to:

$$\bar{a} H |H'\rangle + \hbar \omega \bar{a} |H'\rangle = H \bar{a} |H'\rangle$$

Using the identity  $H |H'\rangle = H' |H'\rangle$ , this becomes:

$$(H' + \hbar \omega) \bar{a} |H'\rangle = H \bar{a} |H'\rangle$$

Therefore,  $H |R\rangle = (H' + \hbar \omega) |R\rangle$  ;  $|R\rangle = \bar{a} |H'\rangle$  (cannot be a null ket)

Similarly,  $H |S\rangle = (H' + 2\hbar \omega) |S\rangle$  ;  $H' + 2\hbar \omega$  is always an eigenvalue

NPTEL logo is visible in the bottom left corner of the whiteboard image.

Then H prime plus h cross omega is always an eigen value. I write down is always an eigen value. So if H prime is an eigen value, H prime plus h cross omega is always an eigen value because ket R can never be a null ket. You will have to do this yourself once and then it will become easy and therefore, we finally, obtain the remarkable result. Just by using operator algebra that the eigen value spectrum,

(Refer Slide Time: 40:10)

$$H|H'\rangle = H'|H'\rangle$$
$$H' = \frac{1}{2} \hbar \omega, \frac{3}{2} \hbar \omega, \dots$$
$$= \left(n + \frac{1}{2}\right) \hbar \omega ; n = 0, 1, 2, \dots$$
$$H|n\rangle = \left(n + \frac{1}{2}\right) \hbar \omega |n\rangle$$

3	—	3⟩	$\frac{7}{2} \hbar \omega$
2	—	2⟩	$\frac{5}{2} \hbar \omega$
1	—	1⟩	$\frac{3}{2} \hbar \omega$
n=0	—	0⟩	$\frac{1}{2} \hbar \omega$

H operating on H prime, the solution of this equation is that H prime can take the values of half h cross omega, 3 halves h cross omega to infinity. It cannot be terminated anywhere, so there are infinite number of eigen values. Therefore, we write this as n plus half h cross omega where n is equal to 0, 1, 2, 3 etcetera, and we label the eigen values. The states are therefore, depend, so we have this n is equal to 0, we represent this by ket 0. This is n is equal to 1 and we represent this by the state ket 1, and then n is 2, which is ket 2. Then 3, which is ket 3, so if n is 3, and then the eigen value is 7 by 2 of h cross omega. This is 5 by 2 h cross omega and 3 by 2 h cross omega and half of h cross omega.

So, we get the same eigen value spectrum, as we had obtained by solving the Schrodinger equation, and we write this down as H n, the eigen value equation for the linear harmonic oscillator problem is written as n plus half h cross omega ket n.

(Refer Slide Time: 42:05)

For the LHO

$$H = \frac{p^2}{2\mu} + \frac{1}{2}\mu\omega^2 x^2$$

$$H|n\rangle = (n + \frac{1}{2})\hbar\omega |n\rangle$$

$$n = 0, 1, 2, \dots$$

$$H'|H'\rangle = H'|H'\rangle$$

$$H\{a|H'\rangle\} = (H' - \hbar\omega)\{a|H'\rangle\}$$

$$a|0\rangle = 0$$

$$a\psi_0(x) = 0$$

So, we finally write that for the linear harmonic oscillator the Hamiltonian is equal to  $p$  square by  $2\mu$  plus half  $\mu\omega^2$ ,  $x$  square. Then  $H$ , the eigen value equations are written as  $H|n\rangle$  is equal to  $(n + \frac{1}{2})\hbar\omega|n\rangle$ , where  $n$  takes the values  $0, 1, 2, 3$ , etcetera. So, this represents the complete eigen value spectrum of the harmonic oscillator problem.

Let me tell you a simple example that since  $|0\rangle$  is the ground state,  $|1\rangle$  is the first excited state. So, a  $|0\rangle$ , you see we had said that if  $H|H'\rangle$  is equal to  $H'|H'\rangle$ , then  $H$  operating on a  $|H'\rangle$  was equal to  $H'|H'\rangle - \hbar\omega|H'\rangle$ ; a  $|H'\rangle$ , this was  $p$ . Now, if  $H'|H'\rangle$  is equal to  $\frac{1}{2}\hbar\omega$ , then there cannot be any state below that. Therefore, a  $|0\rangle$  must be a null ket; A  $|0\rangle$  must be a null ket, otherwise there would be an eigen value of  $-\frac{1}{2}\hbar\omega$ , which will violate this inequality that  $H'|H'\rangle$  must be greater than or equal to  $\frac{1}{2}\hbar\omega$ . So, what was  $a$ ? So, if the Schrodinger representation, therefore,  $a\psi_0(x)$  is equal to  $0$ .

(Refer Slide Time: 44:36)

$$a \psi_0(x) = \frac{\mu \omega x + i p}{\sqrt{2\mu\hbar\omega}} \psi_0(x) = 0$$

$$\left[ \mu\omega x + i(-i\hbar \frac{d}{dx}) \right] \psi_0(x) = 0$$

$$\hbar \frac{d\psi_0}{dx} = -\mu\omega x \psi_0(x)$$

$$\frac{1}{\psi_0} \frac{d\psi_0}{dx} = -\frac{\mu\omega}{\hbar} x$$

$$\ln \psi_0(x) = -\frac{\mu\omega}{2\hbar} x^2 + \text{const}$$

$$\ln \psi_0(x) = -\frac{1}{2} \xi^2 + \text{const}$$

$$\xi = \gamma x$$

$$\gamma = \sqrt{\frac{\mu\omega}{\hbar}}$$

$$\psi_0(x) = N e^{-\frac{1}{2} \xi^2}$$

$$\psi_n(x) = N_n H_n(\xi) e^{-\frac{1}{2} \xi^2}$$

$$= N_0 e^{-\frac{1}{2} \xi^2}$$

Let me see what it leads to. So, a was equal to mu omega a psi 0 of x, which is equal to mu omega x plus i p by under root of 2 mu h cross omega, for psi 0 of x must be 0. This is just a constant, so you get mu omega x plus, if I write down i p as minus i h cross d by dx psi 0 of x is equal to 0. So, this i square is minus 1, minus of minus is plus 1. So, you get h cross d psi 0 by dx is equal to, if you take the other side, minus mu omega x psi 0 of x. So, if I divide by psi 0, so you get 1 over psi 0 d psi 0 by dx, minus mu omega by 2, sorry it is h cross into x and that is it.

If I integrate this (Refer Slide Time: 45:57). So, you get log of psi 0 of x is equal to minus mu omega by 2 h cross x square plus a constant of integration. So, psi 0 of x and if you recall that we had by solving the linear harmonic oscillator problem, we introduced a dimensionless variable xi is equal to gamma x, where gamma was equal to under root of mu omega by h cross. So, you have log of psi 0 of x was equal to minus half xi square plus a constant. So, you will get if you write this (Refer Slide Time: 47:01) is the ground state wave function psi 0 of x within a multiplicative constant e to the power of minus half xi square.

Using operator algebra, we are been able to find to determine that we had obtained psi n of x as N of n, H n of xi, e to the power of minus half xi square. Now, for n equal to 0, so this will be N 0, since H 0 of xi will be 1, so e to the power of minus half xi square. So, we obtain the same wave function by using the fact that a psi 0, that since there is the

half  $\hbar \omega$  is the lowest eigen value, we must have a  $\psi_0$  of  $x$  which will be 0 and therefore, we get the long state wave function.

(Refer Slide Time: 48:23)

Handwritten mathematical derivations on a whiteboard:

$$H|H'\rangle = H'|H'\rangle$$

$$H\{a|H'\rangle\} = (H' + \hbar\omega)\{a|H'\rangle\}$$

$\langle m|n\rangle = 0$

$$\langle n|n\rangle = 1$$

$$H|n\rangle = \underbrace{(n + \frac{1}{2})\hbar\omega}_{H'}|n\rangle$$

$$(n - \frac{1}{2})\hbar\omega$$

$$(n - 1 + \frac{1}{2})$$

$$|n\rangle \rightarrow (n + \frac{1}{2})\hbar\omega$$

$$a|n\rangle \rightarrow (n - \frac{1}{2})\hbar\omega$$

$$a|H'\rangle = a|n\rangle = c_n |n-1\rangle$$

$$\langle P| = \langle n|a = c_n^* \langle n-1|$$

Now, we will do a little bit more algebra and we had said that a ket  $H'$  is an eigen ket, if ket  $H'$  is an eigen ket belonging to the eigen value  $H'$ , then a ket  $H'$  is an eigen ket belonging to  $H'$  plus  $\hbar \omega$ . Sorry, it is minus  $\hbar \omega$ ; a ket  $H'$ . Therefore, we had written down  $H|n\rangle$  is equal to  $n$  plus half  $\hbar \omega$ . So, this is my  $H'$ . Therefore, if I reduce minus  $\hbar \omega$ , so this becomes  $n$  minus half  $\hbar \omega$ . So, this is equal to  $n$  minus 1 plus half.

Therefore, a ket  $H'$  or rather a ket  $n$ , must be a multiple of ket  $n - 1$ . I hope you all understand this; ket  $n$  corresponds to the eigen value  $n$  plus half  $\hbar \omega$ . And a ket  $n$ , if it is not a null ket, then this corresponds to an eigen value of  $n$  minus half  $\hbar \omega$ . So,  $n$  has been reduced to  $n - 1$ , therefore, a ket  $n$  must be a multiple of  $n - 1$ .

Let me write this down as ket  $P$ , therefore bra  $P$  is equal to  $n$  a bar, is equal to  $C_n^*$ , bra  $n - 1$ . I forgot to tell you one thing that since these eigen kets belong to different eigen values and since there is only one eigen ket belonging to one eigen value; different eigen kets belonging to different eigen values, must be orthogonal;  $\langle m|n\rangle$  must be 0. We had proved this that since  $H$  is a self adjoint operator, eigen kets belonging to different

eigen values must necessarily be orthogonal. I can always multiply each one of them such that  $\langle n|n \rangle = 1$ . So, we had the orthonormality condition.

(Refer Slide Time: 51:37)

So this is the  $m \neq n$  equal to 0, for  $m$  not equal to  $n$ . This is the orthogonality condition and this follows from the fact that we have different eigen values and eigen vectors corresponding to different eigen values must necessarily be orthogonal. We have proved that eigen vectors belonging to different eigen values must necessarily be orthogonal and since you have  $H|n\rangle = (n + \frac{1}{2})\hbar\omega|n\rangle$ , and you can multiply the equation by  $c$ . Let us suppose, some constant  $H$  times  $|P\rangle$  is equal to  $(n + \frac{1}{2})\hbar\omega|P\rangle$ , where  $|P\rangle$  is a multiple of  $|n\rangle$ . So, any multiple is also an eigen ket. So, you can always choose the multiplicative constant such that  $\langle n|n \rangle = 1$ .

This is the normalization condition and I can put this two together to write down such as  $\langle m|n \rangle = \delta_{mn}$  and that  $\delta_{mn} = 0$ , if  $m$  is not equal to  $n$ ; is equal to 1 if  $m$  is equal to  $n$ . This is known as the orthonormality condition.

Therefore, we had here that a ket  $|n\rangle$  must be for the lower eigen value, a multiple of  $n - 1$ . So, if I denote this by ket  $|Q\rangle$  let us suppose, then  $\langle Q| = c_n \langle n-1|$ . If I multiply this by  $\hbar\omega$  from both sides, so I get  $\langle Q| \hbar\omega = c_n \langle n-1| \hbar\omega$ , which is equal to  $\langle Q| \hbar\omega = c_n \langle n-1| (n - \frac{1}{2})\hbar\omega$ . This is equal to  $\hbar\omega c_n \langle n-1| (n - \frac{1}{2})$ .

minus 1. This is equal to 1 and this is (Refer Slide Time: 54:59) equal to  $H$  minus half  $h$  cross  $\omega$ .

From this point onwards, we will continue in our next lecture, so we will operate this  $H$  on ket  $n$  and we will find that there is  $n$  plus half  $h$  cross  $\omega$ , so half and half cancels out. You will be left with  $n$  square and so we will get  $C_n$  is equal to square root of  $n$ . You may just try to work this out yourself and so that when we come for our next lecture we will go through those. Those are very extremely important relations and they are of extremely importance not only in quantum mechanics but, in laser theory, in quantum optics and in many other diverse areas.

Thank you.
