The JWKB approximation and Applications
Lecture No. # 01
The JWKB approximation

At the end of the previous lecture, we had started discussing on one of the very powerful methods in quantum mechanics in solving a second order differential equation. Since, second order differential equations appear in many diverse areas of physics and engineering.

(Refer Slide Time: 01:10)

$$\frac{d^2 \psi}{dx^2} + k^2(x) \psi(x) = 0$$
$$\psi'' + k^2 \psi(x) = 0 \Rightarrow e^{\pm i k x}$$
$$\psi(x) = A e^{i u(x)}$$
$$\frac{d^2 u}{dx^2}$$
$$u(x) = \pm i \int k(x) dx$$
$$\psi(x) \approx \underline{\psi_0(x)} = A e^{\pm i \int k(x) dx}$$

This is a very powerful method for solving the second order differential equation. Of the type $\frac{d^2 \psi}{dx^2} + k^2(x) \psi(x) = 0$, where $k^2(x)$ is an arbitrary function of x . However, we assume it to be a smoothly varying function of x . It does not change too much. How much is too much? We will quantify that statement as we go along the lecture.

In my last lecture, I had said that when $k^2(x)$ is independent of x , that is let us suppose $k^2(x)$ is just k^2 , then the solutions of this equation are simple exponentials e to the power of plus minus $i k$ times x . This suggested that for ψ of x , we

try out a solution of the form of e to the power of $i u$ of x and we obtain a differential equation satisfied by u . If we neglected terms which are proportional to $d^2 u$ by $d x$ square and this is justified because when k square of x is constant u of x is just $k x$, so u double prime is 0.

Then, we found that if we neglect this term, then we found that u of x would be plus minus i integral k of x $d x$. Therefore, the zeroeth order WKB solution which is ψ of x , the zeroeth order WKB solution is given by a exponential e to the power of plus minus i integral k of x $d x$. Then, we tried to find out the equation that is rigorously satisfied by ψ of x .

(Refer Slide Time: 03:48)

Condition for Validity of the JWKB solution

$$\left| \frac{1}{k} \frac{dk}{dx} \right| \ll k$$

$$\frac{d^2 \psi}{dx^2} + \frac{\omega^2}{c^2} n^2(x) \psi(x) = 0$$

$$k(x) = \frac{\omega}{c} n(x) \quad \frac{\omega}{c} = \frac{2\pi}{\lambda_0}$$

$$\frac{1}{n} \frac{dn}{dx} \ll \frac{2\pi}{\lambda} \quad k^2 = \frac{2\pi}{\lambda} [E - V(x)]$$

$$\Delta n = \lambda \frac{dn}{dx} \ll n(x)$$

We found that this solution will be an accurate solution if 1 over k $d k$ by $d x$ modulus of that is less than k , this is the condition for validity of the JWKB solution.

Now, we also mention that in an inhomogeneous media, when we consider wave propagation in inhomogeneous medium, the field associated with an electromagnetic wave satisfies this equation ω square by c square n square of x $d x$ multiplied by ψ of x $d x$, where n is the refractive index and ω by c is the free space wavelength, ω by c is 2π by λ naught.

Now, therefore, k of x as you can see is just ω by c n of x and therefore, 1 over k $d k$ by $d x$ is just 1 over n $d n$ by $d x$ should be less than the magnitude of this k is 2π by

λ , the local refractive index. Therefore, if I multiply both sides with λ , I will get $\lambda \frac{dn}{dx}$ by λ neglecting the factor of 2π is less than $n \frac{dn}{dx}$ by λ is the rate of change of the refractive index multiplied by wavelength. That means, this quantity on the left hand side is the change in the refractive index in a distance of the order of the wavelength.

So, therefore, this condition tells us that if the refractive index changes slowly, then my WKB solution is valid. The question is how slowly? The answer is that the change in the refractive index should be small in a distance of the order of this is Δn of x change in the refractive index in a distance of the order of the wavelength that should be small compared to the refractive index itself and of course, in quantum mechanics problem k^2 is equal to 2μ by \hbar^2 minus V of x .

Obviously, even if V of x is slowly varying function, but let us suppose I am in a region where the potential energy is close to the total energy than k^2 becomes 0. So, the left hand side becomes infinity points at which V of x becomes E . Those are known as the turning points or rather classical turning points. We will discuss this little later as to why they are called turning points, but near the turning points, the k^2 itself becomes very small. So, therefore, this inequality does not remain valid and the WKB solutions fail. So, this also we will discuss little later.

(Refer Slide Time: 08:04)

$$\begin{aligned} \psi_0(x) &= A e^{\pm i \int k(x) dx} & \psi_0' &= \pm i k \psi_0 \\ \psi(x) &= F(x) \psi_0(x) \\ \frac{d\psi}{dx} &= F' \psi_0 \pm i k F \psi_0 \\ &= [F' \pm i k(x) F(x)] \psi_0(x) \\ \frac{d^2\psi}{dx^2} &= [F'' \pm i k'(x) F(x) \pm i k F'(x)] \psi_0 \\ &\quad + [\pm i k F' - k^2 F] \psi_0 \end{aligned}$$

Now, therefore, the first order the zeroth order WKB solution is ψ_0 of x is equal to $a e^{\pm i \int k dx}$. Now, we want to do better than this. So, let me assume that ψ of x is some function times ψ_0 of x , where ψ_0 of x is given by this and let me find out the differential equation that is satisfied by ψ . So, you have $\frac{d\psi}{dx}$ or ψ' . This is equal to $f' \psi_0 + f \psi_0'$. So, if you differentiate ψ_0' , so this will be $\pm i k$. The differential of integral of k of x dx is just k times ψ_0 , so ψ_0' is equal to $\pm i k \psi_0$. So, this will be $\pm i k' \psi_0 + \pm i k f \psi_0$. So, I can write this down as $f' \psi_0 + \pm i k f \psi_0$. Differentiate this again. So, I get $\frac{d^2\psi}{dx^2}$. This is equal to if I differentiate this, I get $f'' \psi_0 + 2 f' \psi_0' + \psi_0''$. This is equal to $f'' \psi_0 + 2 f' (\pm i k \psi_0) + (\pm i k)^2 \psi_0$. So, that is $f'' \psi_0 + \pm 2 i k f' \psi_0 - k^2 \psi_0$.

So, if I take the $\pm i k f$ inside, so you get $\pm i k f'$. I am here. There should be an f' because when I differentiate this, I will get first k' f plus $k f'$. So, this is $\pm i k f'$ and $\pm i k f'$. Plus minus is just plus i^2 is minus $k^2 f \psi_0$. So, let me write down the, let me combine these two terms and I will obtain, so this term adds up with this term and this term if I take on this side.

(Refer Slide Time: 11:46)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$\frac{d^2\psi}{dx^2} + k^2 F \psi_0 = \left[\frac{d^2F}{dx^2} \pm i k' F \pm 2 i k F' \right] \psi_0$$

$$\frac{d^2\psi}{dx^2} + k^2 \psi = 0$$

We choose $F(x)$

$$\pm i k' F \pm 2 i k F' = 0$$

$$2k \frac{dF}{dx} = -k' F$$

$$\frac{1}{F} \frac{dF}{dx} = -\frac{1}{2k} \frac{dk}{dx}$$

In the bottom left corner of the whiteboard, there is a small circular logo with a sun-like pattern and the text "NPTEL" below it.

So, all right let me do it step by step, $d^2 \psi$ by dx^2 and if I take this side this here, so it will be $+k^2 f \psi$. Then, this is equal to $d^2 f$ by dx^2 and then, $+ \text{minus } i k' f \psi - 2 i k' f \psi$.

Now, as we had assumed that ψ of x is equal to f times ψ_0 , so this is ψ . So, we obtain $d^2 \psi$ by dx^2 plus k^2 of ψ and what I do is that in the first order look at the approximation, I make this, I neglect this term and I still have not chosen the f of x function and I take this equal to 0. So, the right hand side becomes 0. So, therefore, we choose f of x , such that $+ \text{minus } i k' f \psi - 2 i k' f \psi$ is equal to 0. So, therefore, plus minus, this cancels out. So, if I take this term on the right hand side, so I will get $k^2 k' f$ by dx . This term is equal to $-2 k' f$ by dx will become $-k'$ times f .

So, I rewrite this. If I divide this, so I get 1 over $f' f$ by dx is equal to -1 over $2 k'$ times k , that is $-k'$ by dx . So, if I integrate this, I will obtain a very straightforward integration.

(Refer Slide Time: 14:51)

The image shows a whiteboard with handwritten mathematical derivations for I-order JWKB solutions. The equations are as follows:

$$\ln F + \frac{1}{2} \ln k = \text{const}$$

$$+ \ln k^{\frac{1}{2}}$$

$$\ln [F k^{\frac{1}{2}}] = \text{const}$$

$$F(x) = \frac{\text{const}}{\sqrt{k(x)}}$$

$$\psi_1(x) = \frac{A}{\sqrt{k(x)}} e^{\pm i \int k(x) dx}$$

Below the equations, it is written "I-order JWKB solutions". In the bottom left corner of the whiteboard, there is a small circular logo with the text "NPTEL" below it.

So, you will get log of f is equal to if I take it on this side. So, plus half log of k is a constant. Half log k means log of k to the power of half. So, log a plus log b is log $a \cdot b$. So, log of $f k$ to the power of half is a constant and therefore, we obtain that f of x will be equal to constant times under root of k of x .

Therefore, the first order WKB solution is ψ . First order will be of x will be equal to a by under root of $k(x)$ e to the power of plus minus i integral $k(x) dx$. Let me recapitulate that as to what we did. When $k(x)$ is slowly varying, we found that this is the zeroth order WKB solution. Now, we said that we want to do better than this. So, this is the zeroth order WKB solution. So, we assume for $\psi(x)$ a solution of this type $f(x) + \psi_0(x)$ and remember that $\psi(x)$ satisfies this equation $d^2 \psi / dx^2 + k^2 \psi = 0$.

So, we substitute this solution in this equation. So, we first calculated at this stage. We do not know what $f(x)$ is. We will in fact find out what $f(x)$ is. So, we calculated the first differential, we calculated the second differential and we found that at this f times ψ_0 is ψ . So, we obtained that this equation that $d^2 \psi / dx^2 + k^2 \psi = 0$. The left hand side is 0. So, therefore, if once again if we are able to solve this equation $d^2 f / dx^2 + \text{minus } i k' f + \text{minus } 2 i k f' = 0$, if we are able to solve this equation and then, if we substitute it here, we will obtain a rigorously correct solution of the second order differential equation.

Once again if I am able to solve this equation exactly and obtain an $f(x)$ substitute, then this will be a rigorously correct solution of the Schrödinger equation. We assume that $f(x)$ is a very slowly varying function, so that we neglect the term $d^2 f / dx^2$ and we choose $f(x)$, so that this term is equal to 0. So, you have plus minus $i k' f + \text{minus } 2 i k f' = 0$. We solve this equation and we find that $f(x)$ comes out to be constant times under root of $k(x)$. So, we finally obtain this as the first order JWKB solutions. These are the first order JWKB solutions.

(Refer Slide Time: 20:20)

$$\frac{d^2 \psi}{dx^2} - k^2(x) \psi(x) = 0$$
$$\psi(x) \approx \frac{A}{\sqrt{k(x)}} e^{\pm \int k dx}$$
$$\frac{d^2 \psi}{dx^2} - k^2 \psi = 0 \Rightarrow \psi = e^{+kx} e^{-kx}$$

e^{+kx} exp. amp solution as $x \rightarrow \infty$
 e^{-kx} " decaying " as $x \rightarrow \infty$

In fact, in all everywhere, the second order is so difficult that everywhere one uses only this type of solutions. These are known as therefore the JWKB solutions. Now, we had assumed k square of x to be positive. Let us suppose if k square of x is negative, we have an equation like this minus k square of x ψ of x equal to 0. If we have an equation like this, we can again solve it in a exactly similar manner and we will obtain the WKB solution as constant. So, say a by square root of k x , but since there is a minus sign here instead of $i k x$, it is the plus or minus integral k dx . Either it will be an exponentially amplifying solution or it will be an exponentially decaying solution.

These solutions are oscillatory solutions in terms of sin. Sin as you all know that if $d^2 \psi$ by dx^2 if the constant is positive, then the solutions are either I can write it as $\sin k x$ or $\cos k x$ or I can write it in terms of plus minus $i k x$. So, these are the oscillatory JWKB solutions. On the other hand, if I have an equation of this type $d^2 \psi$ by dx^2 minus k square ψ of x is equal to 0, then it has two solutions. One is e to the power of plus k x if k is a constant which is an exponentially amplifying solution as x goes to infinity and e to the power of minus k x which is an exponentially decaying solution.

(Refer Slide Time: 22:57)

e^{+kx} is an exp. decaying $x \rightarrow -\infty$
 e^{-kx} amplifying $x \rightarrow \infty$

LHO $V(x) = \frac{1}{2} \mu \omega^2 x^2$

$$\frac{d^2 \psi}{dx^2} + \frac{2\mu}{\hbar^2} \left[E - \frac{1}{2} \mu \omega^2 x^2 \right] \psi(x) = 0$$

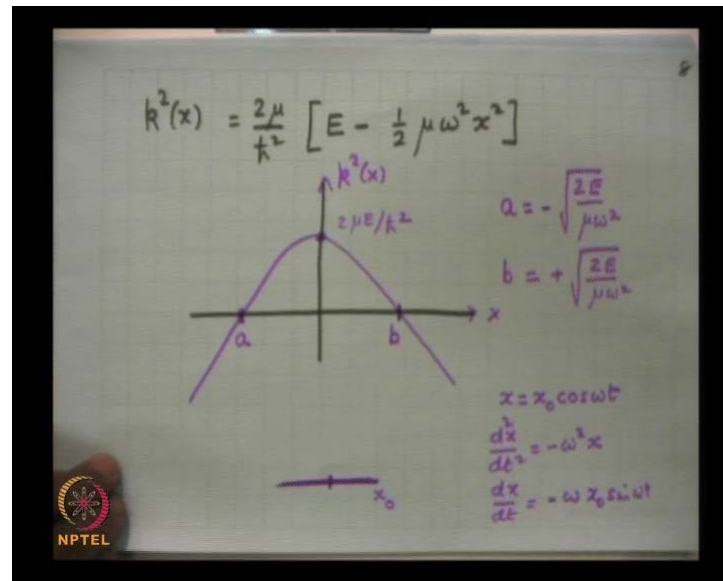

$$k^2(x) = \frac{2\mu E}{\hbar^2} - \frac{\mu^2 \omega^2}{\hbar^2} x^2$$

NPTEL

So, you must remember that e to the power of plus kappa x is exponentially amplifying solution as x goes to infinity and e to the power of minus kappa x is an exponentially decaying solution as x goes to infinity. However, if x goes to minus infinity, then exponential plus kappa x is an exponentially decaying solution as x goes to minus infinity. Similarly, e to the power of minus kappa x is an exponentially amplifying solution as x goes to minus infinity. Both are exponential solutions whereas, when k square x is positive, you have what are known as oscillatory solutions. So, these are the complete JWKB solutions. The question is how do we use them?

Now, let me consider a simple problem that the linear harmonic oscillator problem and you have for the linear harmonic oscillator v of x is equal to half mu omega square x square. Now, therefore, Schrödinger equation is $d^2 \psi$ by $d x$ square plus 2μ by h cross square e minus v of x . So, in this particular case, it is so much. So, half mu omega square x square ψ of x is equal to 0. So, my k square of x is given by this k square of x is equal to $2 \mu e$ by h cross square minus μ square omega square by h cross square x square.

(Refer Slide Time: 25:13)

So, therefore, if I plot this, so my k^2 of x , let me rewrite. It is equal to 2μ by h cross square e minus half μ ω^2 x^2 . Now, let us suppose e is positive, then how will this function look like. If you plot this, then it will be an inverted parabola. So, at x is equal to 0 k^2 , I am plotting k^2 of x as a function of x . So, at x is equal to 0 , it has a positive value equal to $2\mu e$ by h cross square. So, this is $2\mu e$ by h cross square.

Then, at two points, then it starts decreasing with x and these are known as the turning points, where k^2 of x is 0 . So, let us suppose this point is a , this is x is equal to b as you can immediately find out that a is equal to minus of under root of $2e$ by $\mu\omega^2$ square and b is equal to plus under root of $2e$ by $\mu\omega^2$ square. These are known as the turning points because in a classical oscillator, let us suppose I have a classical simple pendulum which is oscillating like this. Now, let us suppose that the maximum amplitude of the classical oscillator is x_{naught} . So, at this point the kinetic energy is so let us suppose x . The vibrations are x is equal to $x_{\text{naught}} \cos \omega t$. So, my d^2x by dt^2 is equal to minus ω^2 of x and dx by dt is equal to if I differentiate, that is minus $\omega x_{\text{naught}} \sin \omega t$.

(Refer Slide Time: 28:33)

The image shows a whiteboard with handwritten equations in purple ink. The equations are:
$$x = x_0 \cos \omega t$$
$$\frac{dx}{dt} = -\omega x_0 \sin \omega t$$
$$KE = \frac{1}{2} \mu \omega^2 x_0^2 \sin^2 \omega t$$
$$PE = \frac{1}{2} \mu \omega^2 x_0^2 \cos^2 \omega t$$
$$E = \frac{1}{2} \mu \omega^2 x_0^2$$
$$x_0 = \pm \sqrt{\frac{2E}{\mu \omega^2}}$$

There is also a small diagram to the right of the equations showing a horizontal line with a vertical tick mark in the center. The left end is labeled $-x_0$ and the right end is labeled $+x_0$. An NPTEL logo is visible in the bottom left corner of the whiteboard.

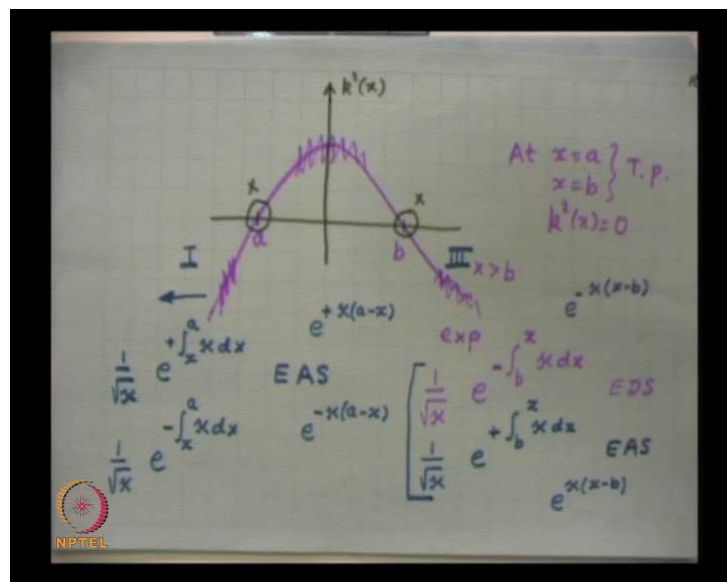

So, the kinetic energy, let me write this again that x is equal to $x_0 \cos \omega t$ and therefore, the velocity $\frac{dx}{dt}$ is equal to $-\omega x_0 \sin \omega t$. So, therefore, its kinetic energy is equal to $\frac{1}{2} \mu \omega^2 x_0^2 \sin^2 \omega t$ and the potential energy is $\frac{1}{2} \mu \omega^2 x_0^2 \cos^2 \omega t$. So, that is $x_0^2 \cos^2 \omega t$.

So, the total energy is equal to $\frac{1}{2} \mu \omega^2 x_0^2$. So, as we all know that if a particle of mass m or mass μ is making a simple harmonic motion, then at the point x_0 , the kinetic energy is 0 and it turns back. So, this point x_0 which is equal to $\pm \sqrt{\frac{2E}{\mu \omega^2}}$, where E is the total energy of the oscillator which is independent of time. E is kinetic energy plus potential energy and that is $\frac{1}{2} \mu \omega^2 x_0^2$.

So, x_0 is the point where the kinetic energy is 0, the total energy is potential and therefore, it turns back. So, therefore, the point $+x_0$ and $-x_0$ are known as the turning points of the oscillator, where the kinetic energy becomes 0 and therefore, the particle turns back. Let us suppose, I have a particle, I have a tennis ball which is climbing up the hill. Now, what will happen is that if you roll the tennis ball, it goes up and then, it turns back. At this point the kinetic energy becomes 0. So, here also the classical oscillator when it reaches the maximum displacement point, the kinetic energy is 0 and the particle turns back.

So, this x naught is equal to plus minus $2u$ by μ , sorry $\mu\omega^2$ by μ . ω^2 are known as the classical turning points. So, in this figure, in this diagram you can see that at the point at x is equal to a and at x is equal to b k^2 of x is 0 and the turning points at x is equal to a and at x is equal to b . Now, I have the condition for the validity of the JWKB solution is 1 over k d k by d x . The modulus of that is should be less than k . So, around this regions, where k is 0, this condition is not satisfied. So, we have the WKB solutions in this region, we can have WKB solutions in this region and we can have WKB solutions in this region, but not near the turning points and therefore, how do we use these solutions.

(Refer Slide Time: 32:41)

So, let me discuss this point once again that let me draw this potential energy distribution and let us suppose, it is something like this. So, I plot k^2 of x and you have like this. These are the two turning points. At the turning points at x is equal to a and at x is equal to b , k^2 of x is 0. These are known as the turning points.

So, my WKB solution is valid here, WKB solution is valid here, WKB solution is valid here, but not in this region. In this region, WKB solutions are not valid. So, if I know the solution in this region, how do I go here or if I know the solution in this region, how do I go here or if I know the solution here, how do I go here. These are done through what are known as the connection formulae and we will discuss the, first of all we will state what are the connection formulae, use them in solving problems and may be at the end of this

lecture, the next lecture may be when we finish JWKB approximation, we will give the theory behind the connection formulae.

First of all, let us suppose that let me write down the solution in this region here, x is greater than d , but k square of x is negative. So, my solutions are exponential solutions and we can write the exponential solutions as $1/\sqrt{k} e^{-\int b dx}$. This is an exponentially decaying solution because if $kappa$ were constant, then the upper limit is x . So, this will be $e^{-kappa x - b}$ and as x tends to infinity, this will be an exponentially decaying solution.

So, similarly $1/\sqrt{kappa} e^{+\int b dx}$ is an exponentially amplifying solution because if $kappa$ was a constant, if I take it out of the integral, so this becomes $kappa x - b$. Now, these are the JWKB solutions in region 3, far away from this turning point. Let us consider region 1. The solutions are $1/\sqrt{k}$. Now, here x is less than a . So, I write these down solutions as $e^{+\int b dx}$. Now, you see that if $kappa$ was a constant, then this will be $e^{+kappa a - x}$ and as x goes to minus infinity. This becomes exponentially amplifying solution.

Similarly, $1/\sqrt{kappa} e^{-\int b dx}$ here x is less than a $kappa d x$ here if I take $kappa$ to be a constant. So, you will have $e^{-kappa a - x}$. So, this will be $e^{-kappa x}$. So, this is a as x goes to minus infinity, this becomes an exponentially decaying solution.

(Refer Slide Time: 38:29)

The whiteboard shows the following equations:

$$k^2(x) \frac{A}{\sqrt{k}} e^{i \int k dx} + \frac{B}{\sqrt{k}} e^{-i \int k dx}$$

$$\psi_{JWK} = \frac{A_1}{\sqrt{k}} \sin \left[\int k dx + \phi \right] + \frac{A_2}{\sqrt{k}} \cos \left[\int k dx + \phi \right]$$

Additional notes on the whiteboard include:

$$e^{ikx} \quad e^{-ikx}$$

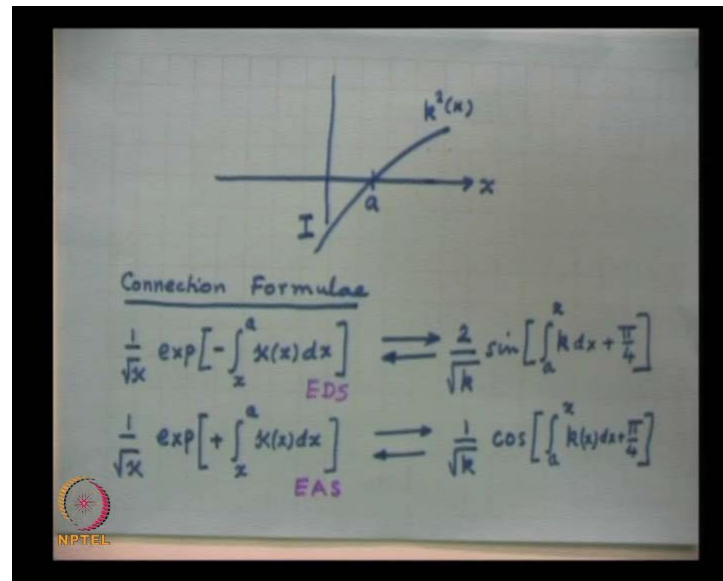

$$\sin kx \quad \cos kx$$

An NPTEL logo is visible in the bottom left corner of the whiteboard image.

Now, let me first mention that you have here when k square of x is positive, the two independent solutions are $\frac{A}{\sqrt{k}} e^{i \int k dx}$ and $\frac{B}{\sqrt{k}} e^{-i \int k dx}$. I can take any linear combination also. For example, when k square is constant, I can write the solution as $e^{i k x}$ and $e^{-i k x}$ or I can write down this as $\sin k x$ and $\cos k x$. That is also well behaved, that is also a legitimate solution.

So, I can write this down as $\frac{A_1}{\sqrt{k}} \sin \left[\int k dx + \phi \right]$ and the other independent solution I can take as $\frac{A_2}{\sqrt{k}} \cos \left[\int k dx + \phi \right]$. x can be at the top or at the bottom. It does not really matter. We will see $k dx + \phi$. So, the general solution is the sum of this. So, this is the general JWKB solution.

(Refer Slide Time: 40:20)

So, let us consider the connection formula when the exponential solutions are to the left and oscillatory solutions are to the right.

So, let us suppose there is a turning point at a , there is a turning point at x is equal to a . This is my x and this is k square of x . K square of x passes through 0 . It is positive on right side. So, here you have oscillatory solutions, here there is exponential solution. So, the connection formulae are $\frac{1}{\sqrt{x}} \exp\left[-\int_x^a k(x) dx\right]$ because in this region, this is the first region. Let us suppose for x less than a , so $kappa$ of x dx . This goes over to there is a factor of 2 , there 2 by root k sin of integral a to x k of x dx . Let me just write it down as k dx plus π by 4 .

So, this is the exponentially decaying solution in region 1 far away from the turning point. This is the oscillatory solution to the right far away to the right of the turning point x is equal to a . Similarly, an exponentially amplifying solution. So, this is under root of k . This you must remember, I remember them, so you must also remember them x to a $kappa$ of x dx . Once you remember the correction formulae, then the use of the WKB approximation is really extremely simple and very elegant and this goes over to 1 over root k . It is a cos function \cos a to x k of x dx k of x dx plus π by 4 .

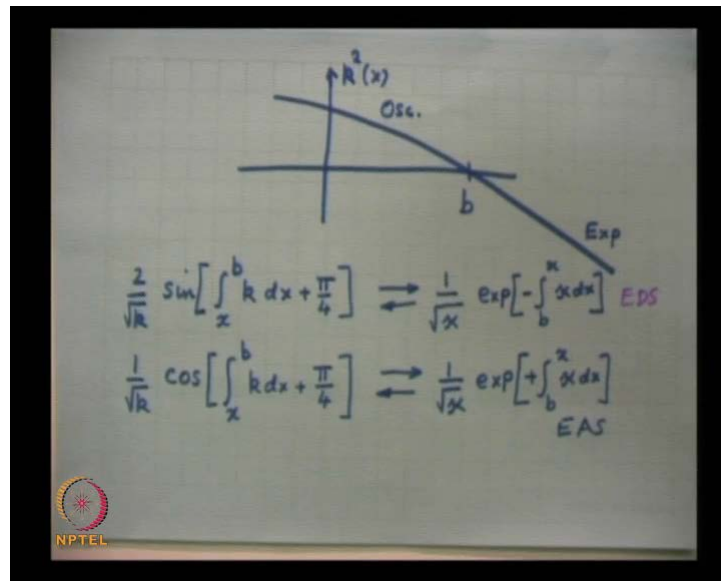

(Refer Slide Time: 43:40)

So, this is the exponentially decaying solution and this is the exponentially amplifying solution. To the left of the turning point, I have drawn a picture. Let me show that to you. So, you have a turning point at x is equal to a . Now, near the turning point, the JWKB solutions are not valid. So, **beyond** little on the right of the turning point, where k square of x is positive, you have trigonometric or sinusoidal JWKB solutions. Beyond a certain distance to the left of the turning point, you have exponential JWKB solutions. This is the variation that I have assumed. It is a smoothly varying function, but it passes through 0 at x is equal to a and these are the two connection formula.

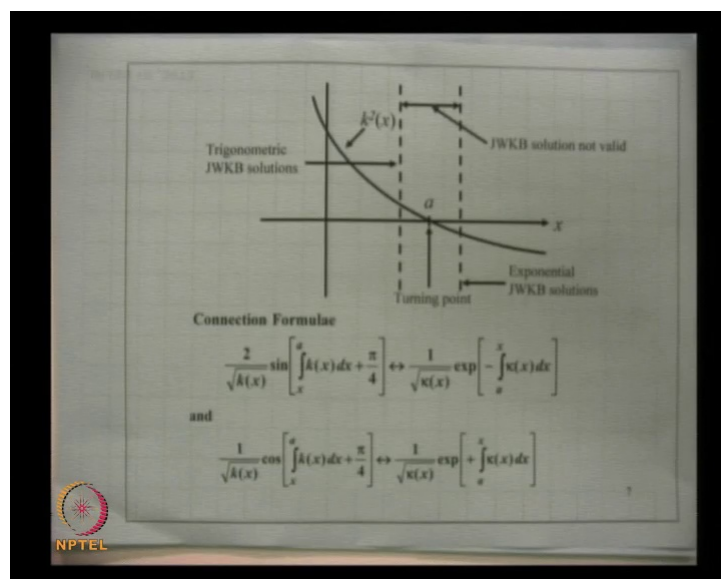

If you have an exponentially decaying solution here, it will go over to the sin function plus π by 4. This phase is important. On the other hand, if there is an exponentially amplifying solution here because if κ was constant, then this would be e to the power of minus κx and as x extends to minus infinity, this will be an exponentially amplifying solution. So, the solution on the left is exponentially decaying solution and the solution to the left is an exponentially amplifying solution and that is equal to 1 over root k . That goes over. I have not given you the proof of the connection formulae and I hope to give you the proof at the end of the next lecture, but right now, you take it for granted. So, once again you do not know the solution near this part, you do not know the solution near this part. You only know the solution far to the left of the turning point.

(Refer Slide Time: 46:01)

So, these are the solution and so these are the solutions far to the right of the turning. What happens if I have a k square of x variation in which there are variations like this. So, let us suppose this is a turning point and you have oscillatory solutions here because k square of x is positive here, k square of x is positive here and k square of x is negative here. So, here, these are exponential solutions and here, they are oscillatory solutions. So, here we will write like this. In this region, we will write 2 by root k 2 by root k \sin of please see the limits now x is now less than d . So, it is x to b k d x k of x d x plus π by 4 . This goes over to the exponentially decaying solution.

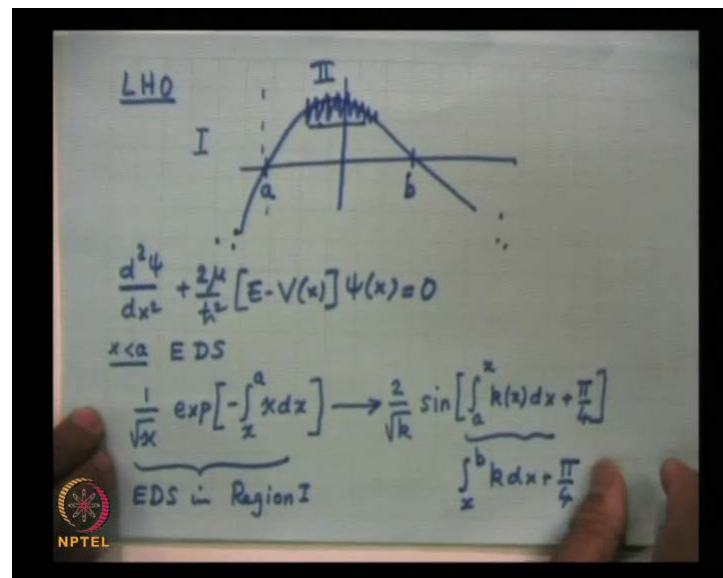

(Refer Slide Time: 48:17)

So, this is $\frac{1}{\sqrt{k}}$ exponential minus integral b to x κdx . This is the exponentially decaying solution and the cos term $\frac{1}{\sqrt{k}}$ cos integral x to b κdx plus π by 4, this goes over to $\frac{1}{\sqrt{k}}$ exponential plus b to x κdx . This is an exponentially amplifying solution. So, here I have shown this again the turning point. Here I have shown as a does not matter. So, what I have tried to show here is that in this region near the point x is equal to a κ square of x is 0. So, in this region, κ square is small and therefore, the JWKB solutions are not valid.

In this region κ square of x is less than 0. So, you have exponential solutions. In this region, κ square of x is positive. So, you have exponential solutions, I mean sinusoidal solutions. So, what are the connection formula, what solution will go over to an exponentially decaying solution and what solution on the left will go over to an exponentially amplifying solution? I am just giving you the answer without proof. Hopefully, I will give you the proof later and the answer is that $\frac{2}{\sqrt{k}}$ $x \sin x$ to a κdx plus π by 4 goes over to an exponentially decaying solution. This I had written down in the previous slide also and this $\frac{1}{\sqrt{k}}$. If you have a term like this, then this will go to an exponentially amplifying solution.

(Refer Slide Time: 50:03)

Now, let us solve a problem. Let me consider the linear harmonic oscillator problem which we have been doing large number of times, the linear harmonic oscillator. So, you have linear harmonic oscillator type. So, you have a κ square of x variation which is

something like this as I had discussed. So, it has two turning points at x is equal to a and at x is equal to b . Now, I want to find out the Eigen values of the problem. Eigen values correspond to the bound state. That means, $d^2 \psi$ by $d x$ square plus 2μ by h cross square e minus v of x . I am solving this problem. So, the boundary conditions are that x must go to 0 as x tends to infinity and as x tends to minus infinity, so I must start. I must have an exponentially decaying solution here and I must have an exponentially decaying solution here.

So, the trick is that in region 1, that is x less than a , I start with an exponentially decaying solution here. I then go over to this region and then, I look towards this turning point and go over to this region and find the coefficient of the exponentially amplifying solution and that we must set equal to 0. Let me do this. So, for x less than a , if you want to have an exponentially decaying solution, then the solution is 1 over root κ as we discussed just a few minutes back minus x to a κ $d x$.

This is the exponentially decaying solution in region 1. I write this. It goes over to in region 2. In this region far away from the turning point to 2 by root κ sin of a to x κ of x $d x$ plus π by 4 . So, I have stated with an exponentially decaying solution here and using the connection formulae, I have been able to get a solution here. Now, I want to get a solution in this region. So, for that if this is let us suppose the point b , then I must write the solution in terms of x to a or this turning point x to b κ $d x$ plus π by 4 . The argument has to be like this and then only I can hop over this turning point and go to this side.

(Refer Slide Time: 54:09)

$$\frac{2}{\sqrt{k}} \sin \phi$$

$$\phi = \int_a^x k(x) dx + \frac{\pi}{4} \quad \left(\int_x^b k dx + \frac{\pi}{4} \right)$$

$$= \int_a^b k(x) dx + \frac{\pi}{4} - \left(\int_x^b k dx + \frac{\pi}{4} \right) + \frac{\pi}{4}$$

$$= \theta + \frac{\pi}{2} - \left(\int_x^b k(x) dx + \frac{\pi}{4} \right)$$

$$\frac{2}{\sqrt{k}} \cos \left[\theta - \left(\int_x^b k(x) dx + \frac{\pi}{4} \right) \right]$$

So, let me tell you. So, instead of this, I must have expression like x to b k d x plus π by 4 . So, it will become clear in a moment. So, in the second region, my solution is 2 by root k sin of ϕ , where ϕ is equal to integral a to x k of x d x plus π by 4 . So, a point is here and b point is here. So, I want to now write the integral in terms of x to b k d x plus π by 4 . So, what I do is I write this down as a to b k of x d x plus π by 4 and then, I write minus x to b k d x plus π by 4 . I have added a term minus π by 4 . So, this I add π by 4 .

So, what I had done is I have written integral a to x as a to b minus x to b . So, this becomes let me put this is equal to θ . So, this becomes θ plus π by 2 plus π by 4 minus integral x to b k of x d x plus π by 4 . So, if I take the sin of this thing sin of π by 2 plus α is cos α , so I will get 2 by root k . This term, please see this 2 by root k cos of θ minus this whole quantity x to b k of x d x plus π by 4 . So, now I will write this as cos a cos b plus sin a sin b . We will continue from this point onwards in our next lecture.
