**Lecture No # 06**  
**Expectation Values and the Uncertainty Principle**

In the last lecture we had obtained a physical interpretation of the wave function. The Schrodinger equation has written in the terms of wave function  $\psi$  and we had said we had derived an equation of continuity from which we could interpret  $\text{mod } \psi^2 d\tau$  as the probability of finding the particle between in the volume element  $d\tau$ .

(Refer Slide Time: 00:56)

The image shows handwritten mathematical derivations on a grid background. The text is as follows:

$$\int |\Psi|^2 d\tau = 1$$
$$\langle x \rangle = \frac{\int x |\Psi|^2 d\tau}{\int |\Psi|^2 d\tau} = 1$$

$\Psi$  is normalized  $\int |\Psi|^2 d\tau = 1$

$$\langle x \rangle = \int \Psi^* x \Psi d\tau$$

An NPTEL logo is visible in the bottom left corner of the slide.

Actually we obtain that this is this should be proportional to the probability but then if we normalize this in the entire space, so then we can interpret  $\text{mod side square } d\tau$  as the probability of finding the particle in the volume element  $d\tau$ . So associated with the particle if I want to find out the expectation value of any quantity  $x$  then I just have to multiply by the probability density function and integrate over the dais space actually the integration is something like this that the all the integration is over the entire space  $x$

mod side square d tau divided by integral mod psi square d tau. Because mod psi square d tau is proportional to the probability but, if this integral is 1 which will assume from now on words so will assume from now on words that the function psi is normalized and if the wave function is normalized then mode psi square this integral over the entire space is 1 and therefore the denominator is one. So I will obtain  $\langle \psi^* \psi \rangle$  and I will write this for reasons which will become clear in a moment as  $\langle \psi^* \psi \rangle$  is equal to integral  $\psi^* \psi d\tau$ . Why do we write it this particular way it will become clear in 1 minute.

(Refer Slide Time: 03:23)

The image shows a handwritten derivation on a grid background. At the top, the time-dependent Schrödinger equation is written:  $\psi^* i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \nabla^2 \psi + V\psi$ . Below this, both sides are multiplied by  $\psi^*$  and integrated over all space  $\tau$ . The left side is identified as the expectation value of energy  $\langle E \rangle$ . The right side is split into two terms: the first term,  $\int \psi^* \left(-\frac{\hbar^2}{2m} \nabla^2\right) \psi d\tau$ , is identified as the expectation value of kinetic energy  $\langle \frac{p^2}{2m} \rangle$ , and the second term,  $\int \psi^* V \psi d\tau$ , is identified as the expectation value of potential energy  $\langle V \rangle$ . The final result is  $\langle E \rangle = \langle \frac{p^2}{2m} \rangle + \langle V \rangle$ . Below this, the expectation value of momentum  $\langle p_x \rangle$  is given by the formula  $\langle p_x \rangle = \int \psi^* \underline{p}_x \psi d\tau$ . An NPTEL logo is visible in the bottom left corner of the slide.

Now we have the time dependent Schrodinger equation with 3 dimensional Schrodinger equation  $i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \nabla^2 \psi + V\psi$ , what I do is that I multiply this equation by  $\psi^*$  and then integrate. So I obtain **so I obtain** on the left hand please see this carefully. This integration is over the entire space so the integral is really at 3 dimensional integral  $\psi^* \psi d\tau$  integration is over the entire space and then we will have  $\psi^* \left(-\frac{\hbar^2}{2m} \nabla^2\right) \psi$  plus  $\psi^* V \psi$ . On the last term this term is just the potential energy function multiplied by the probability density function integrated over the entire space, so this quantity is the expectation value of the potential energy. Classically we know that the total energy is the kinetic energy plus the potential energy so we should expect that the expectation value of the total energy must be equal to the expectation value of kinetic energy plus the expectation value of the potential energy. So therefore,

this quantity should be the expectation value of total energy and this quantity should be the expectation value of the kinetic energy. And now we see that the quantity within the bracket within this within the bracket is the operator corresponding to the energy  $E$ . Similarly  $p^2$  is  $p_x^2 + p_y^2 + p_z^2$  so this is  $-\hbar^2 \nabla^2$ , so this quantity within the brackets is the operator corresponding to  $p^2$ . So therefore, we get the recipe that if I want to find the expectation value for example,  $p_x$  then what I have to do is I will write down  $\int \psi^* p_x \psi d\tau$  where  $p_x$  is the operator representation of  $p_x$ . So therefore from above we obtain the recipe that if I want to find out the expectation value of  $x$   $y$  and  $z$  this equal to this all these integrals are 3 dimensional integral  $\int \psi^* \psi d\tau$  they are normalized, similarly for  $y$ , similarly for  $z$  for  $p_x$  the expectation value of  $p_x$  is equal to  $\int \psi^* p_x \psi d\tau$  which is equal to  $\int \psi^* (-i\hbar \frac{\partial}{\partial x}) \psi d\tau$

(Refer Slide Time: 07:55)

Handwritten equations on a blue grid background:

$$\begin{aligned} \langle x \rangle &= \int \psi^* x \psi d\tau \\ \langle p_x \rangle &= \int \psi^* p_x \psi d\tau \\ &= \int \psi^* (-i\hbar \frac{\partial}{\partial x}) \psi d\tau \\ \langle p_x^2 \rangle &= \int \psi^* (-\hbar^2 \frac{\partial^2}{\partial x^2}) \psi d\tau \\ \langle \Theta \rangle &= \int \psi^* \Theta \psi d\tau \\ p_x &= p_x p_x = -\hbar^2 \frac{\partial^2}{\partial x^2} \end{aligned}$$

An NPTEL logo is visible in the bottom left corner of the slide.

If I want the expectation value of  $p_x^2$  then  $p_x^2$  as we know is  $p_x$  times  $p_x$  so  $-\hbar^2 \frac{\partial}{\partial x} \frac{\partial}{\partial x}$  that is  $-\hbar^2 \frac{\partial^2}{\partial x^2}$ , so the  $p_x^2$  the expectation value is  $\int \psi^* (-\hbar^2 \frac{\partial^2}{\partial x^2}) \psi d\tau$ . And the general recipe if I want to measure a

dynamical variable  $o$  then the expectation value of this I represent that by the corresponding operator and put between psi star and psi  $o$  psi d tau this is the general recipe for determining the expectation value. So therefore, we must remember these 2 3 equations the expectation value is of course very simple the expectation value of  $p_x$  is psi star on the left and psi on the left right the  $p_x$  represented by this differential operator representation and this is for  $p_x$  square and if you want write the kinetic energy then I have to just divide by  $2m$ . In general if I want to make a measurement of a dynamical variable represented by  $o$  and if I want to find out the expectation value then all that I have to do is to integrate psi star  $o$  psi d tau. I am assuming that the wave function is normalized with this we will try to give an exact formulation of the uncertainty principle between  $x$  and  $p_x$  that I in **in** statistical theories if there is a variation of a parameter then the spread is measured in terms of mean square deviation and that is  $\Delta x$  is defined as  $\sqrt{\langle x^2 \rangle - \langle x \rangle^2}$  the average of  $x^2$  minus  $x$  average square under the root so this is the spread the uncertainty in  $x$

(Refer Slide Time: 11:47)

$$\Delta x = \sqrt{\langle x^2 \rangle - \langle x \rangle^2}$$

$$\Delta p_x = \sqrt{\langle p_x^2 \rangle - \langle p_x \rangle^2}$$

$$\Delta x \Delta p_x \geq \frac{\hbar}{2}$$

$\frac{979}{980} \cdot \frac{981}{980} \text{ cm/s}^2$   
 $\frac{979.9}{980.0} \cdot \frac{980.1}{980.0}$

Now for example, let me give you an example of an experiment I measuring the acceleration due to gravity I use a simple pendulum and in three random measurement I change the length of the pendulum and in three random measurements I get nine seventy nine meter per second square nine eighty and nine eighty one. The mean of that is nine eighty centimeter per second square now I use a kater's pendulum to make a measurement of acceleration due to gravity but, there I get 3 values like 979.99 80.0 and

980.1 if I take a mean of that again I will get nine eighty. But there is a difference between these two here the uncertainty is much more than this here the uncertainty of the order of 1 and here the uncertainty is the order of 0.1 how do we express this uncertainty this we express in terms of carrying out let us suppose the spread will be you will write down is will be the average value of g square minus the square of the average value and then take this square root. In this case it will come out to be point 8 or 0.9 and in this case it will come out to be 0.08 or 0.09 or 0.1 above something like that so this spread the variation if I make a large number of measurement the variation is usually expressed by this quantity  $\Delta x$  I take the average of the square minus square of the average. Similarly if I make the measurement of the momentum then I will write it as the square root of the average of the square of the momentum, I am considering only the x component I only considering the x component so  $p_x$  square minus  $p_x$  whole square I will show that for any wave function the product  $\Delta x \Delta p_x$  is greater than or equal to  $\hbar$  cross by 2 so this is an exact statement for the uncertainty relation.

Now in order to derive that we will first prove an inequality and this is known as Schrodinger inequality and inequality I have  $f^* f d\tau$  multiplied by  $g^* g d\tau$  where all functions f and g are well behaved square integrable functions

(Refer Slide Time: 15:27)

$$\frac{\int f^* f d\tau}{a} \frac{\int g^* g d\tau}{c} \geq \frac{1}{4} \left[ \int (f^* g + f g^*) d\tau \right]^2$$

$$b = \int f^* g d\tau$$

$$b^* = \int f g^* d\tau$$

$\lambda$ : real

$$\int |\lambda f + g|^2 d\tau \geq 0$$

$$\int (\lambda f + g)(\lambda f^* + g^*) d\tau \geq 0$$

$$\lambda^2 \frac{\int f^* f d\tau}{a} + \lambda \frac{\int (f^* g + f g^*) d\tau}{b + b^*} + \frac{\int g^* g d\tau}{c} \geq 0$$

NPTEL

this is always greater than or equal to one by four brackets integral  $f^* g$  plus  $f g^* d\tau$  whole square. Now this quantity we denote by a this quantity we denote by c and we

write down that  $b$  is equal to  $\int f^* g \, d\tau$  therefore,  $b^*$  is equal to the complex conjugate of this is  $\int f g^* \, d\tau$ . All these integrals are over the entire space and they are all three dimensional integrals. Now in order to prove this inequality where  $f, g$  are all arbitrary functions, arbitrary means single valued and integrable functions and in order to prove that I consider a parameter  $\lambda$  which is real  $\lambda$  I assume to be real and I have I consider the integral  $\lambda f + g$  mod square  $d\tau$ . Now since  $\lambda$  is real so this quantity is positive because it is the square of the modulus and integrated over the entire space so this must be always greater than or equal 0 positive always positive because this is the integrand is a positive indefinite quantity. So let me write down the integrand so that is equal to  $\lambda f + g$  multiplied by  $\lambda f^* + g^*$ , because  $\lambda$  is itself a real quantity so I multiply this out so I get  $\lambda^2 f^* f + \lambda f^* g + \lambda f g^* + g^* g$ . So I multiply integrate this  $d\tau$  and this is always positive definite, so I integrate it here I integrate it here so I integrate it here all integrals over entire space so this is always positive definite so this is  $a$  as I have renounced here and this is  $b$  plus  $b^*$  and this is  $c$ , so I obtain  $\lambda^2 a + \lambda(b + b^*) + c$  will be always greater than zero.

(Refer Slide Time: 20:00)

$$\lambda^2 a + \lambda(b + b^*) + c > 0$$

$$ax^2 + bx + c = 0$$

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$(b + b^*)^2 < 4ac$$

$$ac > \frac{1}{4}(b + b^*)^2$$

$$\int f^* f \, d\tau \int g^* g \, d\tau \geq \frac{1}{4} \left[ \int (f^* g + f g^*) \, d\tau \right]^2$$

This means if you plot this as a function of  $\lambda$ , it will have no zeros and therefore for example, as you will know that you see if I consider an equation like this  $ax^2 + bx + c$  the roots of this equation are  $x$  is equal to  $\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$

of  $b^2 - 4ac$  divided by  $2a$  but, if this quantity is always positive then there are no real roots and therefore, this square must be less than or equal to zero. So that this quantity is negative and therefore, it will have no real roots, so this quantity  $b^2 - 4ac$  must be less than or equal to zero. So you get  $a$  must be greater than or equal to  $\frac{b^2}{4c}$  and that is my inequality that  $f^* a$  was equal to  $f^* \hat{H} \psi$  that is  $f^* \hat{H} \psi$  was equal to  $g^* g$  so this must be greater than or equal to  $\frac{b^2}{4c}$  that is  $\int f^* g$  plus  $\frac{1}{4} \int f^* g$  whole square. So therefore, we have been able to derive what is known as Schrodinger inequality

(Refer Slide Time: 22:53)

$$f = p\psi = -i\hbar \frac{\partial \psi}{\partial x} \quad \langle x \rangle = 0 \quad \langle p_x \rangle = 0$$

$$g = i\hbar x\psi$$

$$\int g^* g d\tau = \int \psi^* x^2 \psi d\tau = \langle x^2 \rangle$$

$$\int f^* f d\tau = \int i\hbar \frac{\partial \psi^*}{\partial x} (-i\hbar \frac{\partial \psi}{\partial x}) dx dy dz$$

$$= \hbar^2 \int \frac{\partial \psi^*}{\partial x} \frac{\partial \psi}{\partial x} dx dy dz$$

$$= \hbar^2 \left[ \psi^* \frac{\partial \psi}{\partial x} \right]_{-\infty}^{+\infty} - \int \psi^* \frac{\partial^2 \psi}{\partial x^2} dx \dots$$

Now we assume that we assume that  $f$  is equal to  $p\psi$  and  $p\psi$  is equal to  $-i\hbar \frac{\partial \psi}{\partial x}$  and  $g$  is equal to  $i\hbar x\psi$ , then you can see we will discuss the easiest case first  $g^* g$  so  $g^* g$  will be  $i$  times  $-i$  plus 1, so this will be  $g^* g$  will be  $x^2 \psi^* \psi$  so this will be  $\psi^* x^2 \psi$  so this is my the expectation value of  $x^2$  we will we are considering the special case although the more general case can be considered very easily that the expectation value of  $x$  is 0 I can always choose the origin in such a way that expectation value of  $x$  is zero. we further assume the expectation value of  $p$  is zero. So  $g^* g$  will be  $i$  times  $-i$  becomes one so  $\psi^* x^2 \psi$  so this is the expectation value of  $x^2$ . Similarly,  $f^* f$  will be equal to if you see this  $f^* f$  will be  $\hbar^2 \frac{\partial \psi^*}{\partial x} \frac{\partial \psi}{\partial x}$  that is  $\hbar^2 \frac{\partial^2 \psi^*}{\partial x^2} \psi$

delta psi by delta x multiplied by d tau that is d x d y d z. So I times minus i is one so h cross square if I take outside h cross square and I just consider the x part of the integration the y and z part is also there so I get delta psi star by delta x into delta psi by delta x d x **actually** into d y d z but, I omitting that in this moment. So this I integrate by parts and I obtain h cross square this I take as the integrating factor psi star delta psi by delta x from minus infinity to plus infinity minus integral psi star delta two psi by delta x square d x of course multiplied by d y d z and d y d z integrations are also there.

(Refer Slide Time: 27:29)

$$\int f^* f d\tau = \int \psi^* \left( -\hbar^2 \frac{\partial^2 \psi}{\partial x^2} \right) dx = \langle p^2 \rangle$$

$$p_x^2 \psi = -i\hbar \frac{\partial}{\partial x} \left( -i\hbar \frac{\partial}{\partial x} \right) \psi$$

$$= -\hbar^2 \frac{\partial^2 \psi}{\partial x^2}$$

$$\int g^* g d\tau = \langle x^2 \rangle$$

Now for a localized wave packet for a particle which is localized in a small region of space this wave function has to vanish at infinity so this term vanishes at the upper and lower limit and I obtain only this so I finally, obtain I finally, obtain integral f star f d tau is equal to psi star minus h cross square I take this inside delta 2 psi by delta x square d x similarly, d y and d z. So this is the expectation value of p x square because you remember that p x is minus i h cross delta by delta x and p x square will be minus i h cross d by delta x so p x square psi is minus i h cross delta by delta x into psi, so this will minus **minus** plus h cross minus **minus** plus and then this I square is minus so this is equal to minus h cross square delta two psi by delta x square. So this quantity becomes the expectation value of p x square but, I will just write p square and the third term on right side will be if you remember the therefore, so f star f d tau is p square g star g d tau we are just now obtained g star g d tau was equal to x square will be the term on the right hand side.

(Refer Slide Time: 29:42)

$$\frac{1}{4} \int (f^* g + f g^*) d\tau$$

$$f = -i\hbar \frac{\partial \Psi}{\partial x}$$

$$g = i\hbar \Psi$$

$$I = \frac{1}{4} \int (f^* g + f g^*) d\tau$$

$$= \frac{1}{4} \int \left[ i\hbar \frac{\partial \Psi^*}{\partial x} i\hbar \Psi + i\hbar \frac{\partial \Psi}{\partial x} i\hbar \Psi^* \right] d\tau$$

$$= -\frac{\hbar}{4} \int \left[ \frac{\partial \Psi^*}{\partial x} \Psi + \frac{\partial \Psi}{\partial x} \Psi^* \right] d\tau$$

$$\frac{\partial}{\partial x} (\Psi^* \Psi) = \frac{\partial \Psi^*}{\partial x} \Psi + \Psi^* \left[ \Psi + x \frac{\partial \Psi}{\partial x} \right]$$

$$= \frac{\partial \Psi^*}{\partial x} \Psi + \Psi^* \Psi + \Psi^* x \frac{\partial \Psi}{\partial x}$$

You see in the inequality we had we had 1 over this is f star f this is g star g is greater than equal to one over four f star g plus f g star so let me evaluate this so f star g let me do it in a fresh page that one by four integral f star g plus f g star again d tau is d x d y d z, so f as we may recall was equal to minus i h cross so f as you may recall was minus i h cross delta psi by delta x and g was equal to i x psi so you will have so let me just consider the integrand the integrand is equal to one over f star g plus f g star and this is equal to one over four f star that is i h cross delta psi star by delta x into g that is i x psi plus f that is f is minus I h cross delta psi by delta x you have to do this little carefully and g star is minus i so minus **minus** becomes plus so i x psi star, so this is i times i is minus one and this is i times i is minus one so this becomes minus h cross by four delta by delta x psi star x i plus delta psi by delta x **x** psi star.

Now if you write down this equation this expression delta by delta x psi star x i then this will be please see delta psi star by delta x into x i plus psi star into please see this carefully delta by delta x of these two terms the product of these two terms. And if I differentiate this **if I differentiate this** first I will get psi because the differential coefficient of x is one plus x delta psi by delta x. So you obtain so you obtain if you these two terms are appearing here if you see this carefully this is delta psi star delta x multiplied by x psi plus psi star psi plus psi star x delta psi by delta x, so if you see this **this** term is this term let me encircle them with red so this term is the same as this term

and this term is the same as this term, so this plus this which is the quantity inside the square brackets here is this minus this.

(Refer Slide Time: 34:22)

$$\text{Integrand} = -\frac{\hbar}{4} \left[ \frac{\partial}{\partial x} (\psi^* x \psi) + \psi^* x \psi \right]$$

$$\psi^* x \psi \Big|_{-\infty}^{+\infty}$$

$$\int \psi^* \psi d\tau = 1$$

$$= \frac{\hbar}{4}$$

Therefore, an integrand will become the integrand will become minus  $\hbar$  cross by for delta by delta  $x$  i has to just patiently work this out to straight forward but, it requires a little patience minus  $\psi^* \psi$ . If I integrate this so I have to integrate if I had to integrate this with respect to  $x$  and this with respect to  $dx$  and then  $dy dz$  then the integration over  $x$  will be  $\psi^* x \psi$  from minus infinity to plus infinity, so the wave function is going to vanish at both plus infinity and minus infinity therefore this term will be zero and if the wave function is normalized so  $\psi^* \psi d\tau$  is one is one if the wave function is normalized this your minus sign sitting outside so you will get  $\hbar$  cross by four.

(Refer Slide Time: 36:18)

$$\int f^* f d\tau \int g^* g d\tau \geq \frac{1}{4} \left[ \int (f^* g + f g^*) d\tau \right]^2$$

$$\langle p^2 \rangle \langle x^2 \rangle \quad g = i\hbar \nabla$$

$$\Delta p = \sqrt{\langle p^2 \rangle - \langle p \rangle^2} = \sqrt{\langle p^2 \rangle}$$

$$\Delta x = \sqrt{\langle x^2 \rangle - \langle x \rangle^2} = \sqrt{\langle x^2 \rangle}$$

$$\Delta p \Delta x \geq \frac{\hbar}{2} \quad \langle p \rangle \neq 0$$

NPTEL

So you will get the relation that a that a if I substitute that in a let me **let me** put it that f star we had obtained that f star f d tau **multiplied** multiplied by g star g d tau is greater than or equal to one fourth of this integral f star g plus f g star d tau whole square. So you will obtain so you obtain that that this was equal to if I remember it rightly that one was g star g was equal to I have found that out g star g was equal to x's square and this was equal to p square. So as you know that delta p is equal to under root of p square minus p average whole square i'm assuming p average to be zero therefore, this is equal to I am taking the special case of p average being zero, so this is square root of p square and delta x is equal to under root of x's square minus x average square which is under root of x's square I am assuming I can this I can always choose the origin of my coordinates such that the x average is zero. So this from if I substitute this here I will get the uncertainty relation that delta p delta x is always greater than or equal to h cross by two this is the uncertainty relation that we have proved from the first principles and let me let me give you a few examples. So from the Schwarz's inequality which is written here we have and then by assuming that f is given by g is given by i x I, g was equal to i x i and similarly, we had assumed an expression for f we have been able to prove that only thing that we have assumed is that the expectation value of p is zero and expectation value of x is zero but, expectation of value of x zero is does not mean anything because you can always choose the origin to be such that the expectation value of x is zero but, expectation value of p is zero one can also generalize this for the case when the expectation value of p is not equal to zero.

(Refer Slide Time: 39:53)

$$\Psi(x) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a(p) e^{\frac{i}{\hbar} p x} dp.$$

$$\langle p \rangle = \int \Psi^* p \Psi dx$$

$$= -i\hbar \int \Psi^* \frac{\partial \Psi}{\partial x} dx$$

$$= -\frac{i\hbar}{2\pi\hbar} \int_{-\infty}^{+\infty} dx \left[ \int_{-\infty}^{+\infty} a^*(p') e^{-\frac{i}{\hbar} p' x} dp' \right] \left[ \int_{-\infty}^{+\infty} p a(p) e^{\frac{i}{\hbar} p x} dp \right]$$

Now let me go back having proved the uncertainty principle let me go back to a simple wave packet so the simple wave packet is a one dimensional packet that we had considered that  $\psi$  of  $x$  is equal to  $\frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a(p) e^{\frac{i}{\hbar} p x} dp$ . Now the expectation value of  $p$  as we had discussed earlier is equal to  $\psi^* p \psi$  where  $p$  is the operator representing  $p$  the variable  $p$  and as we all know now that what we have been discussing that this is equal to  $-i\hbar \frac{\partial \psi}{\partial x}$  so what I do is I substitute for  $\psi^*$  here I substitute for  $\psi$  here it is little complicated but, if you work this out it is worth it. So  $\psi^*$  will be complex conjugate of this so let us **do** do this carefully  $-i\hbar$  and then  $2\pi\hbar$  will come here  $2\pi\hbar$ . And now there are three integrals one for  $\psi^*$  another for  $\psi$  and the third one is on  $dx$ , so please see this first integral is over  $dx$  going from minus infinity to plus infinity then we write down the expression for  $\psi^*$   $\psi^*$  will be  $\frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a^*(p') e^{-\frac{i}{\hbar} p' x} dp'$  so this will be a star  $p$  a star  $p$   $E$  to the power of minus  $i$  by  $\hbar$  cross  $p$   $x$   $dp$  the limits are from minus infinity to plus infinity and then  $\Delta \psi$  by  $\Delta x$  so let me do it with a red pen so  $2\pi\hbar$ , I have already taken outside so I will have minus infinity to plus infinity, if I differentiate with respect to  $x$  then I will get a  $p$  inside so I get  $p$  times  $a$  of  $p$   $e$  to the power of  $i$  by  $\hbar$  cross  $p$   $x$   $dp$ . Now here I have to be very careful till now it is all right if I first integrate this and then integrate this and then carry out this integration but, I am going to jumble up the integration then this  $p$  has to be distinguished from this  $p$  and therefore, I put a

prime here now I can write all the three integrals together then this p prime will not get confused with this p.

(Refer Slide Time: 44:05)

$$= -\frac{i\hbar}{2\pi\hbar} \int_{-\infty}^{+\infty} dx \left[ \int_{-\infty}^{+\infty} a^*(p') e^{-\frac{i}{\hbar} p' x} dp' \right] \int_{-\infty}^{+\infty} p a(p) e^{\frac{i}{\hbar} p x} dp$$

$$= -\frac{i\hbar}{2\pi\hbar} \int dp \int dp' a^*(p') p a(p) \int_{-\infty}^{+\infty} \dots dx$$

So let me write it down that that this p p will be equal to minus i by h cross by two pi h cross, I carry out this d p and then d p prime collect all the terms which involve only p and p prime and these are a star p prime p a of p and then there is an integral over x, let me write this down what is the integral over x.

(Refer Slide Time: 44:56)

$$\int_{-\infty}^{+\infty} e^{\frac{i}{\hbar} (p - p') x} dx$$

$$\frac{1}{2\pi\hbar} \int_{-\infty}^{+\infty} e^{\frac{i}{\hbar} (p - p') x} dx = \delta(p - p')$$

$$\langle p \rangle = \int_{-\infty}^{+\infty} dp p a(p) \int_{-\infty}^{+\infty} a^*(p') \delta(p - p') dp'$$

$$= \int_{-\infty}^{+\infty} dp p |a(p)|^2$$

So the integral over  $x$  is minus infinity to plus infinity  $dx$   $e$  to the power of  $i$  by  $h$  cross  $p$   $x$  minus  $p$  prime  $x$   $dx$ . So if I take the factor to  $\pi h$  cross this will be minus infinity to plus infinity I am **sorry** I have written  $dx$  twice so  $e$  by  $e$  to the power of  $i$  by  $h$  cross  $p$  minus  $p$  prime into  $x$  into  $dx$  and this as you know is delta of  $p$  minus  $p$  prime. So therefore, in this integral in this integral I have taken this factor here and this factor this integral and I obtain I will obtain minus I am **sorry** in  $i$  that is what I made a mistake that when I differentiated delta  $\psi$  by delta  $x$  I will not get just  $p$  I will get  $i$  by  $h$  cross  $p$  so this will be  $i$  by  $h$  cross **sorry**. So **so**  $i$  by  $h$  cross, so that  $i$  will multiply by  $i$  will become minus one and this will become plus  $h$  cross  $h$  cross I hope you understand what I am trying to say that we had here delta  $\psi$  by delta  $x$  and when I differentiate this with respect to  $x$  then I will get an  $i$  by  $h$  cross times  $p$  into  $E$  to the power of  $i$  by  $h$  cross  $p$   $x$ . So I had forgotten the factor  $i$  by  $h$  cross so  $i$  times  $i$  is minus one minus **minus** is plus and the  $h$  cross will cancel out with this and then so this two factors will go away and this will become plus and this will become two  $\pi h$  cross.

Now this two  $\pi h$  cross I have taken here so I will obtain for expectation value of  $p$  this remarkable result that minus infinity to plus infinity  $dp$  and if I write down  $p$  the  $a$   $p$  star  $a$  star  $p$  prime then delta of  $p$  minus  $p$  prime  $dp$  prime so if I carry out this integration over  $p$  prime then this is just a star  $p$  so I get this as minus infinity to plus infinity  $dp$  **p** mod  $a$   $p$  square.

Handwritten mathematical derivation on a blue grid background:

$$\psi(x) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a(p) e^{\frac{i}{\hbar} p x} dp$$

$$\langle p \rangle = \int \psi^* -i\hbar \frac{\partial \psi}{\partial x} dx$$

$$= \int_{-\infty}^{+\infty} p |a(p)|^2 dp$$

$$\langle p^2 \rangle = \int_{-\infty}^{+\infty} p^2 |a(p)|^2 dp$$

On the right side, there are two small graphs. The top graph shows a triangular probability distribution  $|a(p)|^2$  centered at  $p=0$ , with a peak value of  $A$  and a base extending from  $-\sigma$  to  $\sigma$ . The bottom graph shows a rectangular probability distribution  $|a(p)|^2$  centered at  $p=0$ , with a peak value of  $A$  and a base extending from  $-\sigma$  to  $\sigma$ .

So **so** we have for any wave function  $\psi$  for any wave function  $\psi$  if I write as one over two  $\pi \hbar$  cross integral  $a(p) e^{i p x / \hbar} dp$  from minus infinity to plus infinity then **then** the expectation value of  $p$  will be given by  $\psi^* p \psi$  that is minus  $i \hbar$  cross  $\Delta \psi$  by  $\Delta x$  into  $\Delta x$  and if you we just carried out the entire manipulation entire algebra and we found that this is equal to  $p$  into  $a(p)^2 dp$  therefore. Similarly if I calculate  $p^2$  I will find that this is equal to minus infinity I leave this is an exercise you have to differentiate this twice it is very easy it is very straightforward and you will have a  $p^2 dp$ .

Thus we can interpret  $a(p)^2 dp$  as the probability of finding the momentum between  $p$  and  $p + dp$ , I must add probability of finding the  $x$  component of the momentum between  $p_x$  and  $p_x + dp_x$  therefore, this is also physically obvious because what is an integral **integral** is the superposition of this wave functions and therefore, in this case  $e$  this represents the momentum spread of the wave function the **the the** quantity  $a(p)^2 dp$  represents the momentum spread of the wave function. So if a particle is localized within a distance of the order of  $\sigma$  if this is the wave function then the corresponding momentum spread function  $a(p)^2 dp$  this is say  $\Delta p$   $\Delta x \sim \hbar$  the  $\Delta p$   $\Delta x \sim \hbar$  square will be localized also within a **distance** within momentums spreads function will be of the order of  $\hbar$  cross  $\pi \sigma$ .

$$i \hbar \frac{\partial \Psi}{\partial t} = - \frac{\hbar^2}{2m} \frac{\partial^2 \Psi}{\partial x^2}$$

**Most General Solution**

$$\Psi(x, t) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a(p) e^{\frac{i}{\hbar} \left( px - \frac{p^2}{2m} t \right)} dp$$

So therefore, let me we note down the two terms back we wrote down for the free particle the most general solution was given by this of the time independent of the time dependent Schrodinger equation and here a p represents we have now physically interpreted a p represents the momentum distribution function.

(Refer Slide Time: 52:12)

$$\Psi(x) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a(p) e^{\frac{i}{\hbar} p x} dp$$

$$a(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} \Psi(x) e^{-\frac{i}{\hbar} p x} dx$$

$|\Psi(x)|^2 dx =$  Probability of finding the particle between  $x$  and  $x + dx$

$|a(p)|^2 dp =$  Probability of finding the momentum between  $p$  and  $p + dp$

And this is how from the given form of psi of x I can determine the corresponding a of p by taking the inverse Fourier transform and interpret psi of x mod square d x as probability of finding the particle between x and x plus d x and a p square d p will be the probability of finding the particle or finding the momentum between p and p plus d p.

(Refer Slide Time: 52:59)

$$\psi(x, 0) = \frac{1}{(\pi \sigma_0^2)^{1/4}} e^{-\frac{x^2}{2\sigma_0^2}} e^{\frac{i \hbar p_0 x}{2\sigma_0^2}}$$

$$\int_{-\infty}^{+\infty} |\psi|^2 dx = 1$$

$$\langle x^2 \rangle = \int_{-\infty}^{+\infty} x^2 |\psi|^2 dx = \frac{1}{\sqrt{\pi \sigma_0^2}} \int_{-\infty}^{+\infty} x^2 e^{-\frac{x^2}{2\sigma_0^2}} dx$$

$$x^2 = y$$

$$= \frac{1}{\sqrt{\pi \sigma_0^2}} 2 \int_0^{\infty} y e^{-\frac{y}{2\sigma_0^2}} dy$$

$$= \frac{\sigma_0^2}{2}$$

I conclude today's talk by writing the wave function which is  $\psi(x, 0)$  at  $t$  equal to 0. Let us suppose we wrote down that **we** we consider this two terms back  $\pi \sigma_0^2$  raised to the power of four  $e$  to the power of minus  $x^2$  by two  $\sigma_0^2$   $e$  to the power of  $i$  by  $\hbar$  cross  $p_0$  naught  $x$ . If you calculate this first of all you can easily show that minus infinity to plus infinity  $|\psi|^2 dx$  is one so the function is normalized. I have done this quite a few times I do not want to do. Secondly the expectation value of  $x$  will be the will be  $x$  times  $|\psi|^2 dx$  so  $|\psi|^2$  will be  $e$  to the I can write down under root of  $\pi \sigma_0^2$  and then  $x$  into  $x$   $e$  to the power of minus  $x^2$  by  $\sigma_0^2$  the mod square of this function. This is this will become one and this will become  $e$  to the power of minus  $x^2$  by  $\sigma_0^2$  this limits are from minus infinity to plus infinity and of course, this is an odd function of  $x$  and therefore, the integral is zero.

So the expectation value of  $x$  is 0 the expectation value of  $x^2$  is  $x^2$  here  $x^2$  square here and here you can easily integrate this in terms of gamma function and then you will get one over under root of  $\pi \sigma_0^2$  square two integral zero to infinity and then if you put  $x^2$  is equal to say  $y$  and then carry out the integration you will obtain this to be equal to  $\sigma_0^2/2$ .

(Refer Slide Time: 55:32)

$$\langle x \rangle = 0$$

$$\langle x^2 \rangle = \frac{1}{2} \sigma_0^2$$

$$\Delta x = \sqrt{\langle x^2 \rangle - \langle x \rangle^2}$$

$$\Delta x = \frac{\sigma_0}{\sqrt{2}}$$

So we had we had  $x$  average is zero and  $x$  square average is half sigma zero square therefore, uncertainty in  $x$  will be under root of  $x$  square minus  $x$  average square so this is zero, so this will be sigma zero by root two this is the uncertainty that if you make a measurement of the  $x$  coordinate of the particle then it will be I showed you a wave packet. So the wave packet is such that that it is localized within a distance of sigma zero.

(Refer Slide Time: 56:21)

$$\psi(x, 0) = \frac{1}{(\pi \sigma_0^2)^{1/4}} e^{-x^2/2\sigma_0^2} e^{i \frac{p_0}{\hbar} x}$$

$$\int_{-\infty}^{+\infty} |\psi|^2 dx = 1$$

$$\langle x^2 \rangle = \int x^2 |\psi|^2 dx = \frac{1}{\sqrt{\pi \sigma_0^2}} \int_{-\infty}^{+\infty} x^2 e^{-x^2/\sigma_0^2} dx$$

$$x^2 = y$$

$$= \frac{1}{\sqrt{\pi \sigma_0^2}} \cdot 2 \int_0^{\infty} x^2 e^{-x^2/\sigma_0^2} dx$$

$$= \frac{\sigma_0^2}{2}$$

Now for the wave function that I had written down for the wave function I can write it as I can write it as equal to one over two pi h cross integral a p E to the power of i by h cross p x d p and then take the inverse Fourier transform of of the function.

(Refer Slide Time: 56:44)

$\langle x \rangle = 0$   
 $\langle x^2 \rangle = \frac{1}{2} \sigma_0^2$   
 $\Delta x = \sqrt{\langle x^2 \rangle - \langle x \rangle^2}$   
 $\Delta x = \frac{\sigma_0}{\sqrt{2}}$   
 $a(p) = \left( \frac{\sigma_0^2}{\pi \hbar^2} \right)^{1/4} e^{-\frac{(p-p_0)^2 \sigma_0^2}{\hbar^2}}$   
 $\int p |a(p)|^2 dp = \langle p \rangle = p_0$   
 $\langle p^2 \rangle = p_0^2 + \frac{\hbar^2}{2\sigma_0^2}$   
 $\Delta p = \sqrt{\frac{\hbar^2}{2\sigma_0^2}} = \frac{\hbar}{\sqrt{2} \sigma_0}$   
 $\Delta p \Delta x \sim \frac{\hbar}{2}$

And you will finally, get a p is equal to sigma I leave that an exercise sigma zero square raised to the divided by pi h cross's square raised to the power of one by four raised to the power of one by four e to the power of minus p minus p 0 whole square sigma naught square by h cross's square. So this is if you plot the momentum distribution function then you will find that p mod a p square d p. This will be the average value of p this will come out to be p naught and average value of p square will be p square of this thing and if you carry out this integration one can show that this will come out to be p 0 square plus h cross's square by two sigma naught square, so delta p will be this minus square of this so delta p will be under root of h cross square by two sigma naught square. So this will be h cross by a root to sigma naught, so if I take the product of the two so delta p delta x it will be of the order of h cross of two, so the uncertainty principle the uncertainty principle is contained in the solution of the wave function. So I end by showing the wave

packet that I had shown last time that this is the let us suppose I increase the so the particle is described by this wave function which evolve with time as shown in this diagram as shown in this in the evolution of the wave packet the particle is localized somewhere here and as it propagates it broadens with time that I have not explicitly shown. But you can **you can** carry out the calculations and show that that how the wave function will evolve with time and at each step the product of  $\Delta x$  and  $\Delta p$  is always greater than each cross by two. So we have considered the **the the** definition the **the** of the uncertainty principle we have proved the uncertainty principle given a physical interpretation of the wave function through the equation of continuity and interpreted the wave function corresponding to a Gaussian wave packet . Thank you.
