Simple Solutions of the one Dimensional Schrodinger Equation

Lecture No # 06

One Eigen Values and Eigen Functions of the one Dimensional Schrodinger Equation

Welcome to the ninth lecture on basic quantum mechanics. Today we will be discussing some general issues regarding the Eigen values and Eigen functions, for the one dimensional Schrodinger equation. In my last lecture we had solved the problem of an electron or a proton confined in a potential well of infinite depth. Essentially, we had solved the Schrodinger equation for a particular form of the potential. And as I had mentioned earlier a major part of quantum mechanics, non relativistic quantum mechanics is essentially obtaining the solution of the one dimensional and the three dimensional Schrodinger equation for different forms of the potential.

Basic Quantum Mechanics 9
On Eigenvalues & Eigenfunctions of the
1-dimensional Schrödinger Equation

$$i\hbar \frac{\partial \Psi}{\partial t} = H \Psi(x,t) = -\frac{\hbar^2}{2\mu} \frac{\partial^2 \Psi}{\partial x^2} + \underline{V(x) \Psi}$$
$$\Psi(x,t) = \psi(x) T(t)$$
$$= \psi(x) e^{-iEt/\hbar}$$
$$-\frac{\hbar^2}{2\mu} \frac{d^2 \psi}{dx^2} + V(x) \psi(x) = E \psi(x)$$

NPTEL

So, as we had discussed in our earlier lectures that the one dimensional Schrodinger

equation is given by $\hat{H} \psi = E \psi$ as a function of x and time and $\hat{H} \psi$ of x is equal to \hat{H} cross square by 2μ delta $^2 \psi$ by delta x square plus v of x times ψ . This is known as the one dimensional Schrodinger equation for the **free particle** for the particle in a potential energy function v of x . We assume that the potential energy function is independent of time, depends only on the space coordinates.

And then as we had discussed earlier we can write down the solution using the method of separation of variables, which is given by ψ of x and t of t . We have done this before and we found that the variables indeed separated out and the time dependent part was given by E to the power of minus $i E t$ by \hat{H} cross, where E is a constant. So, if we indeed substitute this we would obtain the following equation that minus \hat{H} cross square by 2μ $d^2 \psi$ by $d x$ square because now the small ψ depends only on the x coordinate plus v of x .

(Refer Slide Time: 03:42)

The image shows a handwritten derivation of the 1D Schrodinger equation and its solution for a particle in a box. The equations are as follows:

$$\Rightarrow \hat{H} \psi = E \psi(x) \rightarrow$$

$$\hat{H} = \frac{p^2}{2\mu} + V(x) = -\frac{\hbar^2}{2\mu} \frac{\partial^2}{\partial x^2} + V(x)$$

Hamiltonian

$$-\frac{\hbar^2}{2\mu} \frac{d^2 \psi}{dx^2} + V(x) \psi(x) = E \psi(x) \quad \checkmark$$

$$\frac{d^2 \psi}{dx^2} + \frac{2\mu}{\hbar^2} [E - V(x)] \psi(x) = 0 \quad \checkmark$$

Below the equations is a diagram of a particle in a box, showing a horizontal line from 0 to a with vertical arrows at the ends.

$$E = E_n = \frac{n^2 \pi^2 \hbar^2}{2\mu a^2} = n^2 E_1; \quad n=1, 2, 3, \dots$$

$$E_1 = \pi^2 \hbar^2 / 2\mu a^2 \quad \psi_n(x) = \sqrt{\frac{2}{a}} \sin \frac{n\pi x}{a}$$

NPTEL

ψ of x is equal to E of x E of ψ . So, this equation is actually an Eigen value equation because we can write this equation in the following form. That $\hat{H} \psi$ is equal to $E \psi$ and where \hat{H} is the Hamiltonian operator which is the kinetic energy p square by 2μ plus v of x and if I substitute for p is equal to minus \hbar cross delta by delta x . So, we will get minus \hbar cross square by 2μ delta $^2 \psi$ by delta x square plus v of x . This operator representation for the total energy this is known as the Hamiltonian this is known as the Hamiltonian of the system. So, my Schrodinger equation is usually written as is written

the time independent Schrodinger equation is written as an Eigen value equation.

So, if I substitute this here. So, as was obtained a few minutes back minus $\frac{\hbar^2}{2m}$ since ψ depends only on the x coordinate. I can replace the partial differential operator by a total differential operator $\frac{d^2 \psi}{dx^2} + V(x)\psi = E\psi$. As I had mentioned earlier this is an Eigen value equation. This is a even this equation is an Eigen value equation. We will find that for a given potential energy distribution only certain discrete or continuum values of E are allowed those are the Eigen values of the problem and corresponding to each Eigen value. There is a wave function those are known as the Eigen functions on the system.

So, we have we can write this equation rewrite this equation just a simple ordering $\frac{d^2 \psi}{dx^2} + 2m(E - V(x))\psi = 0$, where m is the mass of the particle $E - V(x)$. In most textbooks the equation is write at the written either in this form or in this particular form. Now, in my last lecture I had assumed $V(x)$ to correspond to a particle in a one dimensional box. And we had assumed the particle to be confined between x is equal to 0 and x is equal to a . Let us suppose and we had found that the energy Eigen values are given by E_n , which was equal to $n^2 \pi^2 \frac{\hbar^2}{2ma^2}$.

This is equal to $n^2 E_1$, where E_1 is the energy level corresponding to n equal to 1. So, that is the ground state energy value $\frac{\pi^2 \hbar^2}{2ma^2}$. And the corresponding wave function was given by $\psi_n(x)$ was equal to $\sqrt{\frac{2}{a}} \sin \frac{n\pi x}{a}$ where n takes the values 1 2 3 etcetera. Today we will discuss some general properties of the Eigen values and Eigen functions for a given potential energy function $V(x)$ for example, we will show that all Eigen values must necessarily be real. Secondly, we will show that Eigen functions corresponding to different Eigen values are necessarily orthogonal. So, let us first prove that the Eigen values are always real.

(Refer Slide Time: 08:28)

$$\psi_n^* \left[\frac{d^2 \psi_n}{dx^2} + \frac{2\mu}{\hbar^2} [E_n - V(x)] \psi_n \right] = 0 \quad (1)$$

$$\frac{d^2 \psi_n^*}{dx^2} + \frac{2\mu}{\hbar^2} [E_n^* - V(x)] \psi_n^* = 0 \quad (2) \times \psi_n$$

$$\psi_n^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_n^*}{dx^2} + \frac{2\mu}{\hbar^2} (E_n - E_n^*) \psi_n^* \psi_n = 0$$

$$\frac{d}{dx} \left[\psi_n^* \frac{d\psi_n}{dx} - \psi_n \frac{d\psi_n^*}{dx} \right] + \frac{d\psi_n^*}{dx} \frac{d\psi_n}{dx} + \psi_n \frac{d^2 \psi_n^*}{dx^2} - \frac{d\psi_n}{dx} \frac{d\psi_n^*}{dx} - \psi_n \frac{d^2 \psi_n^*}{dx^2} = 0$$

So, we write the Eigen value equation. So, $\frac{d^2 \psi_n}{dx^2}$. Let us suppose for the not state in my previous problem. You remember that we had explicitly determined the energy Eigen values. So, this is my ground state, this is the first excited state, this is second excited state, this is the third excited state n equal to 1, n equal to 2, n equal to 3, n equal to 4 etcetera. So, we assume we do not take a specific form of V of x for a general V of x . We assume that that ψ_n of x is an Eigen function belonging to the Eigen value 2μ by \hbar^2 cross square E_n minus V of x ψ_n of x is equal to 0. I now write the complex conjugate of this equation.

So, if I take the complex conjugate. So, we will have $\frac{d^2 \psi_n^*}{dx^2}$ by $\frac{2\mu}{\hbar^2}$ and \hbar^2 cross are necessarily real quantities. So, you will have 2μ by \hbar^2 cross square and let us suppose E_n can take complex values E_n^* , but the potential energy function is a real function of x . So, the complex conjugate of that is the same as V star of x is equal to V of x multiplied by ψ_n^* of x . So, the second equation number 1 is the Schrodinger equation corresponding to the not Eigen state equation number 2 is the complex conjugate of equation 1. Where we have assumed that the potential energy function is a real function.

What I do is I multiply the first equation and usually the convention is you multiply on the left by ψ_m sorry ψ_n^* . And the second equation on the right by ψ_n and then subtract. So, the left hand side. So, the left hand side the first term will be if you see

this carefully $\psi_n^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_n^*}{dx^2}$ plus 2μ by H cross square. Please see this here also it is $\psi_n^* \psi_n$ here also it is $\psi_n^* \psi_n$. So, if we subtract this from this the v will cancel out. We will have E_n minus E_n^* multiplied by $\psi_n^* \psi_n$ equal to 0 this term. If you write carefully then it would be a total differential d of please see this $\psi_n^* \frac{d \psi_n}{dx} - \psi_n \frac{d \psi_n^*}{dx}$.

Straight forward differentiation of this equation will give the first term will be $\frac{d \psi_n^*}{dx} \frac{d \psi_n}{dx}$. And then the second term will be $\psi_n^* \frac{d^2 \psi_n}{dx^2}$ and the if you differentiate these two terms, then it would be minus $\frac{d \psi_n^*}{dx} \frac{d \psi_n}{dx}$ by $\frac{d \psi_n^*}{dx}$. And then this term will come minus $\psi_n^* \frac{d^2 \psi_n}{dx^2}$. So, obviously, these two terms will cancel out sorry I am sorry this two terms will cancel out. This term will remain I am sorry. So, these two terms will be $\psi_n^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_n^*}{dx^2}$ square minus this. So, this quantity is rigorously equal to this. So, what I do is I integrate this plus I integrate this plus I integrate this. So, I will obtain I will if I if I integrate a total differential of a quantity multiplied by dx of course.

(Refer Slide Time: 14:18)

$$\begin{aligned} \psi_n^*(x) \frac{d \psi_n}{dx} - \psi_n \frac{d \psi_n^*}{dx} \Big|_{-\infty}^{+\infty} + \frac{2\mu}{\hbar^2} (E_n - E_n^*) \int_{-\infty}^{+\infty} |\psi_n|^2 dx &= 0 \\ = 0 & \\ \left(\frac{2\mu}{\hbar^2} \right) (E_n - E_n^*) \int_{-\infty}^{+\infty} |\psi_n|^2 dx &= 0 \\ \underbrace{\int_{-\infty}^{+\infty} |\psi_n|^2 dx}_1 & \\ E_n^* &= E_n \quad \text{All eigenvalues of } H \text{ are real} \end{aligned}$$

So, we will get $\psi_n^* \frac{d \psi_n}{dx} - \psi_n \frac{d \psi_n^*}{dx}$ this plus 2μ by H cross square. I can take this outside and then integral mod ψ_n square dx . So, this is equal to 0. So, from minus infinity to plus infinity. So, this I take the limits from minus infinity to plus infinity for any practical problem. When you have a localized particle the

wave function and its derivative must go to 0 at the boundary; these are the boundary conditions of the problem. So, this quantity at both the limits will be 0. So, this will be 0.

So, we will obtain this quantity as 0. So, we will have 2μ by H cross square which is just a number, which can be removed. E_n minus E_n star integral minus infinity plus infinity ψ_n star $d x$ is equal to 0. Now, this quantity is positive definite because this is the square of a wave function. In fact, the wave function we always assume to be normalized. So, that this quantity is always equal to 1 we can always assume to be equal to 1. So, therefore, and this is a constant. So, you must have E_n star must be equal to E_n that is all Eigen values of the Schrodinger equation must necessarily be real.

All Eigen values all this is an important result all Eigen values we will come back to it when we discuss the bra and ket algebra, but, all Eigen values of H the Hamiltonian are real and as we will discuss later that if you make a measurement of energy then you will obtain one of the Eigen values of H . So, these are the possible values that we will measure if we make a precise measurement of energy.

(Refer Slide Time: 17:40)

$$E_n \neq E_m \quad \int_{-\infty}^{+\infty} \psi_m^*(x) \psi_n(x) dx = 0 \quad \text{Orthogonality Condition}$$

$$\psi_m^* \times \frac{d^2 \psi_n}{dx^2} + \frac{2\mu}{\hbar^2} [E_n - V(x)] \psi_n(x) = 0$$

$$\frac{d^2 \psi_m^*}{dx^2} + \frac{2\mu}{\hbar^2} [E_m^* - V(x)] \psi_m^*(x) = 0 \quad \times \psi_n$$

$$\psi_m^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_m^*}{dx^2} + \frac{2\mu}{\hbar^2} (E_n - E_m) \psi_m^* \psi_n = 0$$

So, we have proved that the energy Eigen values are real what we will next prove is that that if E_n , if there are two Eigen values E_n and E_m and if these two are not equal then the corresponding wave functions ψ_n and ψ_m . So, we will have ψ_m star $\times \psi_n$ of x $d x$ taken between minus infinity to plus infinity. This will be equal to 0, when this condition is satisfied we say that the two functions are orthogonal. So, this is known as

the orthogonality condition orthogonality condition.

Now, the proof is very simple we write Schrodinger equation for the n th state $\frac{d^2 \psi_n}{dx^2} + 2\mu(H - E_n)\psi_n = 0$ then I write for the m th state. So, $\frac{d^2 \psi_m}{dx^2} + 2\mu(H - E_m)\psi_m = 0$. What we do is we take the complex conjugate of the second equation. So, I take the complex conjugate of the second equation. Of course μ and H are real quantities numbers E_m we have proved just now to be real.

So, E_m is equal to E_m . So, we do not have to do anything there and then we take the complex conjugate here. There is nothing here sorry. So, because E_m is a real number and then what we do is do the same trick. As we had done before multiply this by ψ_m^* on the left the whole equation and multiply this equation by ψ_n on the left right. So, if you subtract if you multiply the second equation by ψ_n of x and then subtract then as we had obtained in my earlier slide. We will obtain $\psi_m^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_m^*}{dx^2} + 2\mu \psi_m^* \psi_n = 0$ please see this $\psi_m^* \psi_n \psi_m^* \psi_n$.

So, v and v are the same. So, these two terms will cancel out. So, I will be left with E_n minus E_m $\psi_m^* \psi_n$ equal to 0. So, what we do next is as we had done in the previous slide I write this as a total differential $d \psi_m^* / dx \psi_n$ minus $\psi_m^* d \psi_n / dx$ let me leave some space here and the same quantity $2\mu \hbar^2 / 2m$ E_n minus E_m $\psi_m^* \psi_m$ I now multiply by dx and integrate from minus infinity to plus infinity.

I now integrate from minus infinity to plus infinity dx this is equal to 0. I had done this in my last slide that if you expand this out there will be four terms two of them will cancel out and the remaining two terms will be this. So, this will be $\psi_m^* d^2 \psi_n$ by dx^2 minus $\psi_n d^2 \psi_m^*$ by dx^2 and then there will be a terms like $d \psi_m^* \text{ by } dx d \psi_n \text{ by } dx$ and $d \psi_n \text{ by } dx d \psi_m^*$ these two terms will cancel out. So, this is the differential of a of a quantity. So, that the integral is just this quantity and.

(Refer Slide Time: 23:42)

$$\psi_m^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_m^*}{dx^2} + \frac{2\mu}{\hbar^2} (E_n - E_m) \psi_m^* \psi_n = 0$$

$$\int_{-\infty}^{+\infty} \left[\psi_m^* \frac{d^2 \psi_n}{dx^2} - \psi_n \frac{d^2 \psi_m^*}{dx^2} \right] dx + \frac{2\mu}{\hbar^2} (E_n - E_m) \int_{-\infty}^{+\infty} \psi_m^* \psi_n dx = 0$$

$$\left[\psi_m^* \psi_n' - \psi_n \psi_m'^* \right]_{-\infty}^{+\infty} = 0 \quad E_n \neq E_m$$

$$\int_{-\infty}^{+\infty} |\psi_n|^2 dx = \text{finite}$$

$$\int_{-\infty}^{+\infty} \psi_m^* \psi_n(x) dx = 0$$

$$\int_{-\infty}^{+\infty} |\psi_n|^2 dx = 1$$

$$\int_{-\infty}^{+\infty} \psi_m^*(x) \psi_n(x) dx = \delta_{mn} = \begin{cases} 0 & m \neq n \\ 1 & m = n \end{cases}$$

Kronecker-delta δ_{mn}

Orthogonality
Normaliza

So, therefore, the left hand side after carrying out the integration will be just $\psi_m^* \psi_n'$ that is the differential of $\psi_n' \psi_m - \psi_n \psi_m'$. Take it between minus infinity to plus infinity. Now, this is 0 because the wave function vanishes at infinity for to be for them to be square integrable and normalisable they must vanish at infinity. So, by square integrable I mean any function ψ_n of x is square integral means $\int_{-\infty}^{+\infty} |\psi_n|^2 dx$ must be finite.

And I will choose a multiplicative constant. So, that this is equal to one. So, a function, which satisfies this equation or this actually the equation. That this quantity the integral should be finite is known as the square integrable function and for a square integrable function. The function itself must vanish at infinity otherwise it is it will not be a square integrable function. So, therefore, the wave function and its derivative must vanish at infinity and. So, therefore, this term will be 0 this will be equal to 0.

So, we will have only. So, if this term is 0. So, I can cancel this out I will get this is equal to zero. So, I will have product of two terms product of two terms if I write this E_n minus E_m multiplied by this, but, I have initially assumed that E_n is not equal to E_m , therefore, this integral must be 0 and this integral minus infinity to plus infinity $\psi_m^* \psi_n dx$ must be 0 when E_n is not equal to E_m . This condition as I had mentioned earlier is known as the orthogonality condition orthogonality condition.

I am assuming that the wave functions are normalized therefore, minus infinity to plus

infinity mod psi n square d x is equal to one. So, this is known as the normalization condition and I can combine both of them to write down this equation integral from minus infinity to plus infinity psi m star of x psi n of x d x is equal to delta m n. Where this term delta m n is known as the kronecker delta function and this is equal to 0 if m is not equal to n and is equal to 1 if m is equal to n.

So, we have derived an extremely important result. That the wave functions belonging to different Eigen values wave functions belonging to different Eigen values are necessarily orthogonal and this is the orthogonality condition. There is one more thing that I would like to mention that we will use this that the that the wave function that the Eigen functions of the Hamiltonian form a complete set of functions; that means.

(Refer Slide Time: 28:41)

Handwritten mathematical derivation on a grid background:

- Top left: $\psi_n(x)$ and $\int_{-\infty}^{+\infty} |\phi(x)|^2 dx < \infty$
- Top right: $\delta_{mn} = 0 \quad m \neq n$
 $= 1 \quad m = n$
- Middle left: $\phi(x) = \sum c_n \psi_n(x)$
- Middle right: $\int_{-\infty}^{+\infty} e^{-y^2} dx = \int_{-\infty}^{+\infty} e^{-y^2} dy$
- Below middle left: $\int \psi_m^*(x) \phi(x) dx = \sum_n c_n \int_{-\infty}^{+\infty} \psi_m^* \psi_n dx$
- Below middle right: $= \sum_n c_n \delta_{mn}$
 $n = m$
 $= c_m$
- Bottom left (boxed): $c_n = \int_{-\infty}^{+\infty} \psi_n^*(x') \phi(x') dx'$
- Bottom center: A hand holding a black marker.
- Bottom left corner: NPTEL logo.

If psi n of x that is suppose the in a particular problem we have a set of wave functions, which are the Eigen functions of the H of the operator H. Then any arbitrarily function say phi of x any arbitrarily well behaved. Well behaved means it has to be single value it should not be infinite anywhere and it should be a square integrable function. So, that is the meaning of the word well behaved. That it should be single valued function at a particular value of x phi of x must have an unique value.

It must not have any infinities it must not go to infinity in at any point and it is a square integrable function that is phi of x d x integral from minus infinity to plus infinity must be less than infinity. This symbol means this inequality means that this integral is finite.

So, such a function is known as a well behaved function and I state without proof that the Eigen functions form a complete set of function that is arbitrary function can be. I will give you examples of that $c_n \psi_n$ of x .

So, this is known as the completeness condition that any arbitrary function can be represented as a sum as a linear combination of the Eigen functions of H . So, how do I determine c_n what we do is I multiply this equation I multiply this equation by ψ_m^* of x dx and then integrate. So, what we will have is that the left hand side becomes ψ_m^* of x ϕ of x dx is equal to summation the sum is over all values of n the c_n ψ_m^* of x ψ_n dx integral from minus infinity all limits are from minus infinity to plus infinity.

But this I have just now proved to be equal to δ_{mn} . So, therefore, this equation becomes right hand side becomes $c_n \delta_{mn}$ sum the summation is over all values of n . So, only the n equal to m term will survive because for all other terms this kronecker delta function is 0. As I had mentioned that δ_{mn} is equal to 0 for m not equal to n and is equal to 1 if m is equal to n . So, therefore, the summation is over n . So, when n takes the value m that term survives.

So, this will be equal to c_m . So, this is how we will determine the coefficient as I have indicated in my earlier lectures also. So, c_m is equal to or I can write down c_n , c_n is equal to integral. And this limits are also from minus infinity to plus infinity ψ_m^* of x ϕ of x dx sorry n this should be n . Now, what I do is next step is I substitute for c_n from here to here, but you must be careful because this is a definite integral over x . This x should not get confused with this x , but since this is a definite integral I can quietly put a prime here.

And then this x and this x can be differentiated. I hope it is clear because this is a function of x and c_n is a constant and c_n is a definite integral. And in a definite integral it does not matter, whether you put write x or y or z . For example, E to the power of minus x square dx from minus infinity to plus infinity is the same as E to the power of minus y square dy . It does not really matter what you what is in both of them are equal to square root of π . So, this x should not get confused with this x and. So, therefore, I quietly put a prime and then I substitute this here. So, I will substitute this expression for c of n in this equation.

(Refer Slide Time: 34:50)

$$\begin{aligned}\phi(x) &= \sum_n \int_{-\infty}^{+\infty} \psi_n^*(x') \phi(x') dx' \psi_n(x) \\ &= \int_{-\infty}^{+\infty} \phi(x') F(x, x') dx' \\ F(x, x') &= \sum_n \psi_n^*(x') \psi_n(x) = \delta(x - x') \\ \phi(x) &= \int_{-\infty}^{+\infty} \phi(x') \delta(x - x') dx' \\ \sum_n \psi_n^*(x') \psi_n(x) &= \delta(x - x') \quad \text{completeness condition} \\ \int_{-\infty}^{+\infty} \psi_m^*(x) \psi_n(x) dx &= \delta_{mn} \quad \text{orthonormality condition}\end{aligned}$$

So, I will obtain please see this carefully that $\phi(x)$ is equal to summed over n and c_n and what is the value of c_n as we had determined earlier minus infinity to plus infinity $\psi_n^*(x') \phi(x') dx'$ multiplied by $\psi_n(x)$. What I will do is I will first carry out the summation and then the integration. So, that all these quantities, which are dependent on n I take this. So, I get is equal to integral from minus infinity to plus infinity please see this carefully $\phi(x')$ and then some function of x, x' dx' . And as you would have noticed that $f(x')$ $f(x, x')$ is the summation of $\psi_n^*(x')$ multiplied by $\psi_n(x)$ summed over n .

If you would recall the earlier lectures 1 of the earlier lectures in, which we had derived the we in, which we had defined the Dirac delta function and that was $\phi(x)$ will be equal to minus of infinity to plus infinity $\phi(x') \delta(x - x') dx'$. So, it picks up the value at x only no matter what the function ϕ mean ϕ is. So, therefore, this function has to be 0 for all values of x other than x' and. So, therefore, this quantity must be the Dirac delta function this condition is often known as the completeness condition. The that is the wave functions the Eigen functions of the Hamiltonian operator form a complete set of orthonormal function.

And we say this through the following equation that summation $\psi_n^*(x')$ $\psi_n(x)$ summed over n is equal to $\delta(x - x')$. So, we have derived two very important relations this is known as the completeness condition. And the other is other is

that $\int_{-\infty}^{\infty} \psi_m^*(x) \psi_n(x) dx$ is equal to δ_{mn} . This is known as the orthonormality condition it combines the orthogonality condition and the normalization condition. So, this is known as the orthonormality condition. So, these limits are also from minus infinity to plus infinity. So, now, in the example that we had discussed in my last lecture lecture 8.

Diagram of a box from 0 to a .

$$E = E_n = n^2 E_1$$

$$E_1 = \frac{\pi^2 \hbar^2}{2\mu a^2}$$

$$\psi_n(x) = \sqrt{\frac{2}{a}} \sin \frac{n\pi x}{a}$$

$$\int_{-\infty}^{\infty} \psi_m^*(x) \psi_n(x) dx = \delta_{mn}$$

$$\phi(x) = \sum c_n \psi_n(x)$$

$$\sum_n \psi_n^*(x') \psi_n(x) = \delta(x-x')$$

Free Particle

NPTL

We consider a particle in a one dimensional box and the domain that we consider was between 0 and a . And we had found that the energy Eigen values are E is equal to E_n square of E_1 , where E_1 is equal to $\pi^2 \hbar^2$ cross square by $2\mu a^2$ these are the Eigen values and as you can see all Eigen values are real. We had also derived that the wave functions are given by under root of normalized wave functions \sin of $n\pi x$ by a . And if you use this you can immediately show that $\int_{-\infty}^{\infty} \psi_m^*(x) \psi_n(x) dx$ if m and n are different then it will be 0. So, this is equal to δ_{mn} . So, we have E_1, E_2, E_3, E_4, E_5 and so on there are infinite number of states.

Infinite number of discrete states and any function, any well behaved function in the region from 0 to a can be represented by can be approximated and this is my Fourier series that $c_n \psi_n(x)$. So, this is something like the Fourier series that you must have learnt in your college. So, the wave functions also form a complete set of functions and. So, therefore, $\int_{-\infty}^{\infty} \psi_n^*(x') \psi_n(x) dx$ summed over n equal to 1 2 3 infinity is equal to $\delta(x-x')$. So, this was the particle in a box problem

that we had done yesterday. Let me consider another problem about 4 5 3 4 lectures back I had discussed the free particle problem now in the free particle problem let me do it on an another sheet V of x is 0 everywhere.

(Refer Slide Time: 42:07)

$$V(x)=0 \quad H = -\frac{\hbar^2}{2\mu} \frac{d^2}{dx^2}$$

$$H\psi = E\psi \Rightarrow \frac{d^2\psi}{dx^2} + \frac{2\mu E}{\hbar^2} \psi = 0$$

$$\psi(x) = \psi_p(x) = \frac{1}{\sqrt{2\pi\hbar}} e^{\frac{i p x}{\hbar}}$$

$$\psi_p^*(x) = \frac{1}{\sqrt{2\pi\hbar}} e^{-\frac{i p' x}{\hbar}}$$

$$\int_{-\infty}^{+\infty} \psi_p^*(x) \psi_p(x) dx = \frac{1}{2\pi\hbar} \int_{-\infty}^{+\infty} e^{\frac{i}{\hbar} (p-p') x} dx = \delta(p-p')$$

So, it is a free particle and the Hamiltonian operator, which is equal to minus H crosses p square by $2 m$ H cross square by 2μ d^2 by $d x$ square plus V of x , but, V of x is 0. So, we had solved this equation and we had found that if I write $H \psi$ is equal to $E \psi$ then we will get $d^2 \psi$ by $d x$ square plus $2 \mu E$ by H cross square ψ is equal to 0. So, if I write $H \psi$ is equal to $E \psi$ then simple manipulations will give this where E is now the Eigen value where it is a number.

So, we write this as p square this quantity as p square and the Eigen functions are ψ of x becomes ψ_p of x this is equal to E to the power of i by H cross p times x . Now, I put because I know this I put a factor $2 \pi \hbar$ cross. So, what are the values of p E has to be positive E has to be positive because I have put because if p if E becomes negative as you can as you can see p square is equal to $2 \mu e$. So, if $p E$ becomes negative then p will become imaginary if p will become imaginary then times i will be something like either plus or minus $kappa x$.

When this happens then the wave function either goes to infinity at plus infinity or minus infinity E to the power of plus $kappa x$ will blow up at x is equal to infinity as x tends to infinity E to the power of minus $kappa x$ will blow up as x tends to minus infinity. So,

that is not possible because if the wave function becomes infinity it is no more square integrable you can no more normalize the wave function. So, therefore, E has to be positive, but, p can be plus or minus. So, for a given value of E there are 2 values of p 1 plus 1 minus we say that there is a 2 fold degeneracy.

So, if you work this out then I can write down that $\psi_{p'}^*(x) \psi_p(x) dx$ will be equal to $\frac{1}{2\pi\hbar} \delta(p - p')$. Please see this if I take a star here make the complex conjugate then this will be minus here and I can write down $\psi_{p'}^*(x) \psi_p(x) dx$ from minus infinity to plus infinity I multiply this. So, I get $\frac{1}{2\pi\hbar} \delta(p - p')$. So, this is the Dirac delta function delta of p minus p' . This is an example, where the Eigen functions form a continuum. In the previous example we had a discrete set of energies we had a discrete set of energies only certain values of energy were allowed in this case we have all possible values of energy from 0 to infinity.

(Refer Slide Time: 47:37)

Energy Eigenvalues $0 < E < \infty$
Continuum

$$\int_{-\infty}^{+\infty} \psi_{p'}^*(x) \psi_p(x) dx = \delta(p - p')$$

$$\phi(x) = \int_{-\infty}^{+\infty} a(p) \psi_p(x) dp$$

$$= \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} a(p) e^{\frac{i}{\hbar} p x} dp$$

$$a(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{+\infty} \phi(x') e^{-\frac{i}{\hbar} p x'} dx'$$

So, we say that the energy Eigen values form a continuum energy Eigen values are 0 less than E can take all values between 0 and infinity. So, they form a continuum and when this happens the orthonormality. Orthonormality condition is represented by this equation $\psi_{p'}^*(x) \psi_p(x) dx$ the kronecker delta symbol is replaced by the Dirac delta function. Also these functions of course, these they are they form a complete set of functions. So, that any arbitrary function ϕ of x can be written as a of p superposition

times $\psi(p)$ of x $\psi(p)$ of x $d p$ and. So, therefore, these limits are also from minus infinity to plus infinity. So, what is $\psi(p)$ of x $\psi(p)$ of x is 1 over $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} \psi(x) e^{i p x} dx$ E to the power of i by $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} \psi(x) e^{i p x} dx$.

So, this is the Fourier transform. So, it is a superposition of the moment of these wave functions and. So, therefore, $\psi(p)$ is given by the inverse Fourier transform which we had discussed in quite a bit of length this will be $\phi(x)$ E to the power of minus i by $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} \phi(x) e^{-i p x} dx$ all limits are from minus. So, for any well behaved function $\phi(x)$ I can always make this expansion because I can always find $\psi(p)$ by carrying out the inverse Fourier transform now I can substitute for $\psi(p)$ in this equation, but, I have to be careful once again this is a definite integral over x and this x should not be confused with this x . So, I must quietly once again put a prime here and I when I substitute that I will obtain if you see this carefully that.

(Refer Slide Time: 50:55)

$$\begin{aligned}
 &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \psi(p) e^{i p x} dp \\
 \psi(p) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \phi(x') e^{-i p x'} dx' \\
 \phi(x) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \phi(x') F(x, x') dx' \\
 F(x, x') &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{i p (x-x')} dp \\
 &= \delta(x-x') \\
 \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{i p (x-x')} dp &= \delta(x-x')
 \end{aligned}$$

That if I substitute $\psi(p)$ from here then you will get $\phi(x)$ is equal to 1 over $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} \phi(x') e^{i p (x-x')} dx'$ and then there will be another function x comma x prime dx' where f of x prime comma x prime is equal to 1 over $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} e^{i p (x-x')} dp$ here 1 over $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} e^{i p (x-x')} dp$ E to the power of i by $\sqrt{2\pi}$ $\int_{-\infty}^{\infty} e^{i p (x-x')} dp$.

This we know that this is the delta function. So, as soon as I substitute it here I get $\psi(p)$ of x . So, this is my completeness condition is no more a sum it is an integral. So, $\psi(p)$ this condition that I represent this is the completeness condition $\int_{-\infty}^{\infty} \psi(p) e^{i p x} dp$.

by H cross p d p from minus infinity to plus infinity is equal to delta of x minus x prime this is the continuum Eigen function of the of this is the completeness condition for the Eigen functions of the operator H .

Handwritten notes on a grid background showing the derivation of momentum eigenfunctions. The notes include the momentum operator $p_{op} \leftrightarrow -i\hbar \frac{d}{dx}$, the eigenvalue equation $p_{op} \psi = p \psi$, and the resulting wavefunction $\psi(x) = \frac{1}{\sqrt{2\pi\hbar}} e^{\frac{i}{\hbar} p x}$. The range of p is given as $-\infty < p < \infty$. The Hamiltonian equation $H\psi = E\psi$ is also written.

I would like to mention one more thing and that is let me consider the momentum operator p op the momentum operator. We had said that the momentum operator can be represented by minus i write it as a total differential and let us try to find out the Eigen functions of the momentum operator. So, I write this as op of ψ is equal to $p \psi$ this is an Eigen value equation for the momentum operator where p is an Eigen value which is just a number. So, we had the Eigen value equation $H \psi$ is equal to $E \psi$ this is the Hamiltonian which is an operator and you find that only certain values of E are allowed these are the Eigen values.

So, you have the momentum operator p op and this is a I want to solve this Eigen value equation. So, I will have minus $i \hbar$ cross $d \psi$ by dx is equal to $p \psi$ where p once again is a number. So, I multiply by i by \hbar cross. So, the left hand side becomes one. So, I get 1 over ψ $d \psi$ by dx is equal to i by \hbar cross times p . If you integrate this. So, you get $\log \psi$ is equal to i by \hbar cross p times x plus a constant.

So, ψ becomes the constant I will choose as one over under root of $2 \pi \hbar$ cross E to the power of i by \hbar cross $p x$. So, these functions ψ of x I write this as ψ_p of x and I have put the factor $2 \pi \hbar$ cross E to the power of i by \hbar cross $p x$, where p can take any value

from plus infinity to minus infinity to plus infinity. These are known as the normalized momentum Eigen functions these are known as the normalized momentum Eigen functions these are the Eigen functions normalized Eigen functions of the momentum operator. Actually these are simultaneous Eigen functions not only of the momentum operator, but $H \psi$ is equal to $E \psi$ for the free particle.

(Refer Slide Time: 56:03)

Handwritten notes on a grid background:

$$\Rightarrow \psi_p(x) = \frac{1}{\sqrt{2\pi\hbar}} e^{\frac{i}{\hbar} p x} \quad -\infty < p < +\infty$$

Momentum Eigenf.

are simultaneous eigen functions of

$$\hat{p}_{op} = -i\hbar \frac{d}{dx}$$

and also of

$$H = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \quad (\text{Free particle})$$

$$\int_{-\infty}^{+\infty} \psi_p^*(x) \psi_{p'}(x) dx = \delta(p-p') \quad \text{ONC}$$

$$\int_{-\infty}^{+\infty} \psi_p^*(x') \psi_p(x) dx = \delta(x-x') \quad \text{CC}$$

NPTEL logo is visible in the bottom left corner of the slide.

So, therefore, we say that ψ_p of x is equal to $1/\sqrt{2\pi\hbar}$ times $e^{i p x / \hbar}$ going from plus minus infinity to plus infinity they are simultaneous Eigen functions, simultaneous Eigen functions of \hat{p}_{op} , which is equal to minus $i\hbar$ cross d/dx and also and also of the Hamiltonian. For the free particle Hamiltonian for the free particle is $\hbar^2/2m$ d^2/dx^2 actually the Hamiltonian has a v of x term. But v of x is 0 this is for a free particle and these wave functions these wave functions are therefore, Eigen functions of \hat{p}_{op} as well as of this. And these wave functions are often known as the momentum Eigen functions momentum Eigen functions.

And they form an orthonormal set that is $\psi_{p'}^* \times \psi_p \times dx$ is equal to the Dirac delta function $p - p'$ and they also all limits are from minus infinity to plus infinity. And they also form an orthonormal completeness ψ_p of x $\psi_{p'}^*$ of x p' ψ_p of x dx this is equal to delta of $p - p'$ sorry p 's x prime here and this is the orthonormality condition. This is the completeness condition let me

rewrite this again this is not I have not written this carefully.

(Refer Slide Time: 58:27)

$$p = -i\hbar \frac{d}{dx}$$

and also $H = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2}$ (Free particle)

$$\int_{-\infty}^{+\infty} \psi_{p'}^*(x) \psi_p(x) dx = \delta(p-p') \quad \text{ONC}$$
~~$$\int_{-\infty}^{+\infty} \psi_p^*(x') \psi_p(x) dx = \delta(x-x') \quad \text{CC}$$~~

$$\int \psi_p^*(x') \psi_p(x) dp = \delta(x-x')$$

Completeness Condition

So, this is integral $\psi_p^*(x')$ $\psi_p(x)$ dp is equal to delta of x minus x' this is the completeness condition. So, this completes the analysis for the free particle problem as well as for the particle in a box. In our next lecture we will discuss first the solutions of the linear harmonic oscillatory problem and then we will derive those solutions thank you.
