Lecture - 21
Longitudinal Modes of a Spherical Mirror Resonator

Welcome to this MOOC on LASERS. We have been discussing about the Longitudinal and Transverse Modes of a Spherical Mirror Resonator. In the last lecture, we saw about the transverse modes and then in particular, the Gaussian mode of the resonator. One last thing remaining is the longitudinal modes of the resonator.

Of course, we had seen the longitudinal modes, but the expression was incomplete without a knowledge of delta zeta. Now, today we will discuss how to determine the delta zeta and hence the longitudinal modes of the spherical mirror resonator.

(Refer Slide Time: 01:01)

Recap: Gaussian Mode of the Spherical Mirror Resonator

→ Given a Gaussian, what is the position of the spherical mirrors to be chosen?

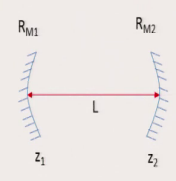

→ $R_{M1}, R_{M2} \rightarrow$ RoC of the mirrors

→ $L \rightarrow$ Separation between the mirrors

$$z_1 = -\frac{L(R_{M2}+L)}{(R_{M1}+R_{M2}+2L)} \dots\dots(1)$$

$$z_2 = z_1 + L \dots\dots(2)$$

→
$$z_0^2 = \frac{-L(R_{M2}+L)}{(R_{M1}+R_{M2}+2L)^2} (R_{M1} + R_{M2} + 2L)(R_{M1} + L) \dots\dots(3)$$

 M R Shenoy 2

A very quick recap: Gaussian mode of the spherical mirror resonator. So, the problem that we had addressed is given a Gaussian what is the position of the spherical mirrors to be chosen? If R_{M1} and R_{M2} are the radius of curvature of the mirrors and L is the separation, then we have already worked out in the last lecture that the position of the mirror $M1$ is z_1 is given by an expression that is equation 1 and the position of mirror $M2$ z_2 is given by z_2 is equal to z_1 plus L .

More importantly, we have got an analytical expression for z_0^2 where z_0 is the Rayleigh range. This is important therefore, for a given resonator which means R_{M1} , R_{M2} and L are given we can determine what is z_0^2 .

(Refer Slide Time: 02:05)

Therefore, we had seen that the expression for resonance frequency can be written in this form ν_q is equal to q times ν_F into $\frac{\Delta zeta}{\pi}$ into $l+m+1$ into ν_F , l and m are the mode numbers, ν_F is the free spectral range.

So, we had seen therefore, that if l and m are 0, then for the spherical mirror resonator this will be the resonance frequency. ν_q is the resonance frequency of the plane mirror resonator which is only the first term ν_q is equal to q times ν_F , but whenever there is a spherical mirror then there is an additional curvature dependent term which is here which leads to a slight shift in the resonance frequency.

And, today we will determine this the magnitude of the curvature dependent term for some resonators.

(Refer Slide Time: 03:11)

Resonance Frequencies → Longitudinal modes of the resonator

$$\rightarrow \nu_q = q \nu_F + \frac{\Delta\zeta}{\pi} (l+m+1) \nu_F$$

→ For the Gaussian beam $l = 0, m = 0$

$$\nu_q = q \nu_F + \frac{\Delta\zeta}{\pi} \nu_F \quad \nu_F = \frac{c}{2nL} \rightarrow \text{Free Spectral range}$$

Curvature dependent correction

→ $\Delta\zeta = \tan^{-1}\left(\frac{z_2}{z_0}\right) - \tan^{-1}\left(\frac{z_1}{z_0}\right)$ can be calculated using Eq. (1), (2), and (3)

M R Shenoy

4

So, as I said we continue to have a recap for the Gaussian beam l is equal to 0, m is equal to 0 and therefore, the resonance frequency is given by this expression, where the second term on the right hand side is the curvature dependent correction, where delta zeta is equal to tan inverse z_2 by z_0 minus tan inverse z_1 by z_0 .

Now, using equations 1, 2, 3 shown in the earlier slide we can determine the positions z_1 , z_2 and z_0 and exactly determine the magnitude of delta zeta. That is what we will do in this lecture.

(Refer Slide Time: 03:58)

Examples:

→ **Symmetric Resonators**

- $R_{M1} = R_{M2} = R_M$
- $Z_1 = -\frac{L(R_M+L)}{(R_M+R_M+2L)} = -\frac{L(R_M+L)}{2(R_M+L)} = -\frac{L}{2}$ → as it should be!
- $Z_2 = Z_1 + L = \frac{L}{2}$

→ $Z_0^2 = \frac{-L(R_M+L)(R_M+R_M+2L)(R_M+L)}{(R_M+R_M+2L)^2}$

$$= \frac{-L(R_M+L)^2(2R_M+L)}{4(R_M+L)^2}$$

$$= \frac{(L+2R_M)L}{4}$$

MPTEL
M R Shenoy

5

So, let me straight away take some examples and illustrate and calculate this delta zeta. So, first if we take symmetric resonators; that means, R_{M1} is equal to R_{M2} is equal to R_M then z_1 is we simply substitute R_{M1} equal to R_{M2} is equal to R_M , then we get z_1 is equal to minus L by 2 , it says as it should be.

So, whenever you have a symmetric resonator which means you have a resonator with spherical mirrors identical spherical mirrors. This will support a Gaussian with its waist exactly midway because it is a symmetric resonator therefore, exactly midway we will have z is equal to 0 ; which means z_1 , if L is the separation here if L is the separation between the mirrors, then z_1 will be equal to minus L by 2 because z equal to 0 , this direction is positive and the other direction is negative.

And therefore, z_2 will be equal to plus L by 2 this is easily comprehensible and we can see that the mathematical expression also gives us that z_1 is equal to minus L by 2 and z_2 is equal to z_1 plus L which is equal to L by 2 . So, z_1 is equal to minus L by 2 and z_2 is equal to plus L by 2 . The z naught square in the case of symmetric resonators we substitute R_{M1} is equal to R_{M2} and gives us to a simple expression which is minus L plus $2 R_M$ into L by 4 .

So, we will use this simple formulae to determine the delta z for some symmetric resonators.

(Refer Slide Time: 05:58)

→ **1. Confocal Mirror Resonator**

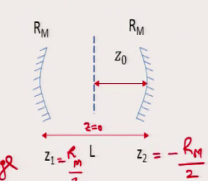

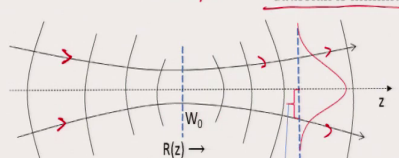

$R_M = -L$

→ $z_1 = -\left(\frac{-R_M}{2}\right) = \frac{R_M}{2}, z_2 = \frac{-R_M}{2}$

→ $z_0^2 = \frac{-L(L + (-2L))}{4} = \frac{L^2}{4} \Rightarrow z_0 = \pm \frac{L}{2}$

→ $R(z) = z + \frac{z_0^2}{z}$ *Rayleigh range*

• $\frac{dR(z)}{dz} = 1 - \frac{z_0^2}{z^2} = 0$ gives $z = \pm z_0 \rightarrow$ Position where the RoC of the Gaussian is minimum *of the wavefront*

$R(z) = z + \frac{z_0^2}{z}$ *Plane*

$W(z) = W_0 \left[1 + \left(\frac{z}{z_0}\right)^2 \right]^{1/2}$

$R(z) \rightarrow \infty$ at $z=0$ & $z = \infty$

NPTEL M R Shenoy 6

So, let us first pick up the confocal mirror resonator. So, the confocal mirror resonator is shown here where L is equal to the radius of curvature of the mirror. So, L is equal to R_M .

So, it is written here. R_M is equal to minus L because these are concave mirrors and therefore, L is equal to minus R_M or R_M is equal to minus L .

So, if we substitute for z_1 we get z_1 is equal to $R_M/2$ and z_2 is equal to minus $R_M/2$, the positions for the confocal mirror resonator. So, here are the positions. So, z_1 is equal to $R_M/2$. So, this is equal to $R_M/2$ and z_2 is equal to minus $R_M/2$. Note that R_M is negative and therefore, z_1 will be negative because this is z is equal to 0.

And, therefore, z_{naught} is equal to if we substitute in the formula we say that z_{naught} is equal to plus minus $L/2$ in other words for a confocal mirror resonator z_{naught} this is called the Rayleigh range; the Rayleigh range. What is its importance we will see in a minute.

The Rayleigh range is at the position of the mirrors itself. So, this is one of the only resonators where the Rayleigh range z_{naught} is equal to z_1 is equal to minus z_2 . So, it is illustrated here z_{naught} is the separation.

Now, what is the importance of z_{naught} ? We know that the radius of curvature of the wave front of the Gaussian beam is given by R of z is equal to z plus z_{naught}^2 by z . If we differentiate therefore, with respect to z to find out where r of z becomes minimum or maximum then we get 1 minus z_{naught}^2 by z^2 .

And, if we put that equal to 0 gives us z is equal to plus minus z_{naught} . So, the importance of z_{naught} is z_{naught} is the position of the beam where its radius of curvature is minimum. We are referring to radius of curvature of the wave front of the wave front of the Gaussian.

This is not radius of curvature of the mirror; this is the radius of curvature of the wave front. So, here it is illustrated in the figure below. So, here is a Gaussian which is propagating from minus infinity to plus infinity. As we see the converging beam has a wave front which is concave, then it becomes plane at the waist and then again it becomes convex and goes ahead.

Now, we know that the wave front is plane. So, R of z is infinity at z is equal to 0, infinity means it is plane; it is plane wave front and this expression tells us that R of z is infinity at z equal to 0 and also at z is equal to infinity which means the wave front is plane on the waist and also at infinity.

And, this we discussed in the previous lecture that therefore, it must pass through a minimum and that minimum corresponds to z naught is equal to 0.

(Refer Slide Time: 09:49)

Confocal Mirror Resonator (contd.)

$\rightarrow \bullet v_q = qv_F + \frac{\Delta\zeta}{\pi} v_F$
 $\rightarrow \bullet \Delta\zeta = \tan^{-1} \left[\frac{z_2}{z_0} \right] - \tan^{-1} \left[\frac{z_1}{z_0} \right]$
 $= \tan^{-1} \left[\frac{L/2}{L/2} \right] - \tan^{-1} \left[\frac{-L/2}{L/2} \right] = \tan^{-1}(1) - \tan^{-1}(-1)$
 $= \left(\frac{\pi}{4} \right) - \left(-\frac{\pi}{4} \right) = \frac{\pi}{2}$

$\rightarrow v_q = qv_F + \frac{\pi/2}{\pi} v_F$
 $v_q = \left(q + \frac{1}{2} \right) v_F$

$v_q = q \left(\frac{c}{2nL} \right)$

Confocal mirror resonator
 Plane mirror resonator

7

So, for the confocal mirror resonator the frequency ν_q is equal to q times ν_F into $\Delta\zeta$ by π into ν_F . Now, $\Delta\zeta$ is equal to $\tan^{-1} z_2$ by z_0 minus $\tan^{-1} z_1$ by z_0 . So, we substitute for z_2 and z_0 ; z_2 is also L by 2 , z_0 is also L by 2 minus \tan^{-1} of minus L by 2 z_1 is minus L by 2 , but z_0 is a value, z_1 is the

coordinate. It is a position here, z_1 and the z naught is z equal to 0 is here and z_2 is here and this is the z axis, this is z .

And therefore, z_1 is the coordinate of the position of mirror m_1 whereas, z naught is simply the distance the distance where the beam has a smallest radius of curvature. So, if we substitute we get $\tan^{-1} \frac{1}{2} - \tan^{-1} \frac{1}{4}$ which is $\frac{\pi}{4} - \frac{\pi}{8}$ which is equal to $\frac{\pi}{8}$. So, this is Δz

And, therefore, if we substitute in the expression for resonance frequency q times νF plus Δz which is $\frac{\pi}{2}$ by π into νF or νq is equal to $q + \frac{1}{2}$ into νF for all values of q . νq for the confocal mirror resonator is $q + \frac{1}{2}$ times νF . νq was equal to q times νF for the plane mirror resonator. Now, for the confocal mirror resonator it is $q + \frac{1}{2}$ into νF which is illustrated now here in this picture, this is the ν axis.

On the ν axis if we say νq $\nu q + 1$ the black colored points positions correspond to the q th order resonance and $q + 1$ th order resonance for the plane mirror resonator. q th order resonance which means q into νF c by $2 n L$ and $q + 1$ th order that is the next one separated by a separation which is νf . So, νF is the free spectral range.

Now, for the confocal mirror resonator resonance frequency of the q th order is shifted by half times νF which means it is exactly midway. So, it is shifted by half times νF and therefore, νq is here for the confocal mirror resonator and $\nu q + 1$ is here for the plane mirror resonator. So, these are for the confocal and this is for the plane.

But, note that the separation is the free spectral range is still νf . So, these are the resonance frequencies of a confocal mirror resonator. We can now determine the resonance frequencies of a concentric mirror resonator for example.

(Refer Slide Time: 13:19)

→ **2. Concentric Mirror Resonator**

$$L = -2R_M$$

$$z_1 = \frac{-L}{2}, z_2 = \frac{L}{2}$$

$$\rightarrow z_0^2 = \frac{-L(L + (-2 \times L/2))}{4} = 0$$

$$\rightarrow \Delta\zeta = \tan^{-1} \left[\frac{z_2}{0} \right] - \tan^{-1} \left[\frac{z_1}{0} \right] = \frac{\pi}{2} - \left(-\frac{\pi}{2} \right) = \pi$$

$$\rightarrow \nu_q = q \nu_F + \frac{\Delta\zeta}{\pi} \nu_F$$

$$\nu_q = (q + 1) \nu_F$$

q^{th} order resonance for the Concentric mirror resonator

M R Shenoy
8

So, let us see. Second example concentric mirror resonator concentric which means the centers center point is common which means the distance from the center point to the mirror 1 is the radius of curvature of the mirror. So, therefore, L the separation between the mirrors is twice the radius of curvature of the mirror, the negative sign again stands for the concave mirror.

Therefore, z 1 is equal to minus L by 2, z 2 is equal to L by 2 which we already know which means it is z 1 is equal to minus R M and z 2 is equal to plus R M. So, therefore, z naught square is equal to comes out to be 0 and then delta zeta will be equal to tan inverse of z 2 by 0 minus tan inverse of z 1 by 0.

So, this is infinity tan inverse of infinity and tan inverse of minus infinity; minus infinity because this is minus z 1 is negative and therefore, it is pi by 2 minus minus pi by 2 which is

equal to pi. So, delta zeta turns out to be pi and therefore, if we substitute in the expression for the resonance frequency of the Gaussian beam then, we get nu q is equal to q plus 1 times nu f.

So, the qth order resonance frequency for the concentric mirror resonator is shifted it is q plus 1 coincides with the q plus 1th order resonance frequency of a plane mirror. So, nu q here and nu q plus 1, the separation is still nu f. So, note that the order is shifted by 1 as compared to the resonance frequencies of the plane mirror.

(Refer Slide Time: 15:22)

3. General Symmetric Mirror Resonator:

$L = 20 \text{ cm}, R_M = -100 \text{ cm}$
 $z_1 = \frac{-L}{2} = -10 \text{ cm}, z_2 = \frac{L}{2} = 10 \text{ cm}$

$\rightarrow z_0^2 = \frac{-L(L + 2RM)}{4} = \frac{-20(20 - 200)}{4} = 900 \text{ cm}^2$
 $z_0 = 30 \text{ cm}$

$\rightarrow \Delta\zeta = \tan^{-1} \left[\frac{10}{30} \right] - \tan^{-1} \left[\frac{-10}{30} \right] = 2 \tan^{-1} \left[\frac{1}{3} \right]$

$\rightarrow \nu_q = q \nu_f + \frac{2 \tan^{-1} \left[\frac{1}{3} \right]}{\pi} \nu_f = q \nu_f + 0.2 \nu_f$

 **NOTE:** For any other (non-symmetric) resonators use Eq. (1), (2) and (3) to obtain the values of z_1, z_2 , and z_0 , and determine ν_q .

M R Shenoy9

Let us take a general symmetric mirror resonator; general here stands for we normally discuss confocal and concentric mirror resonators, but general means you could have any other value and any other L, provided it is a stable resonator.

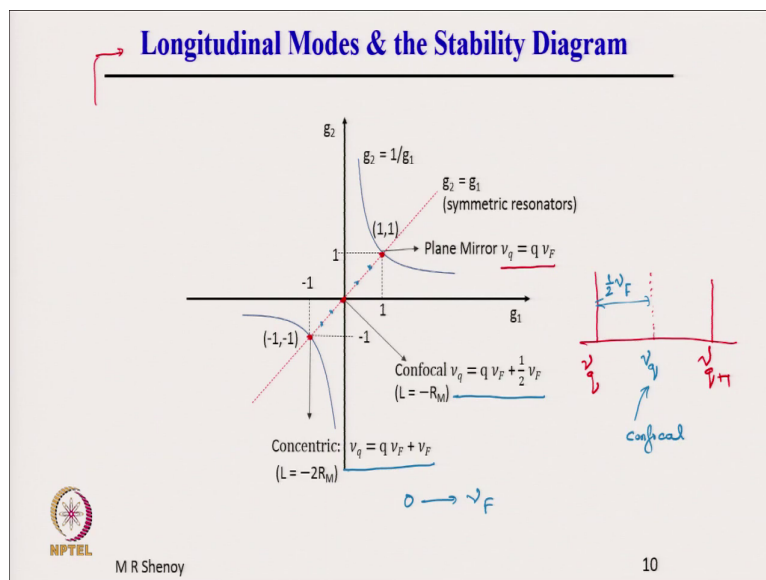

So, what we have chosen is L is equal to 20 centimeter and radius of curvature of the mirror is minus 100 centimeter. So, if we substitute we get z_1 is equal to minus 10 centimeter and therefore, z_2 is equal to 10 centimeter. More importantly z_{naught} square now comes out to be if we substitute here it is 900 centimeter square or z_{naught} is equal to 30 centimeter.

And, we follow the same procedure. Therefore, Δz is equal to $\tan^{-1} z_2 / z_{\text{naught}}$ minus $\tan^{-1} z_1 / z_{\text{naught}}$. With z_1 there is a negative sign here always in a symmetric resonator because the waist is at the midpoint where z is equal to 0 z_1 is negative and this comes out to be twice $\tan^{-1} 1/3$.

So, if we substitute in the expression for ν_q so, ν_q is equal to q times νF plus Δz which is twice $\tan^{-1} 1/3$ divided by π into νF . This term comes out to be 0.2 and therefore, the resonance frequency is q times νF plus 0.2 times νF . We have seen 0.5 times νF for the confocal case and 1 times νF the additional curvature dependent term for the concentric case and here it turns out to be 0.2 times νF .

If we want to take any other spherical mirror resonator that is not necessary symmetric resonator any other spherical mirror resonator then we must use equations 1, 2, 3 to determine the positions z_1 , z_2 and z_{naught} using equation 1, 2 and 3. That is what is stated here for any other non-symmetric resonators use equation 1, 2 and 3 to obtain the values of z_1 , z_2 and z_{naught} and hence determine the resonance frequency ν_q .

(Refer Slide Time: 18:03)

Now, finally, I want to illustrate the positions on this stability diagram. That is why the title is given longitudinal modes and the stability diagram. We have already seen the stability diagram in detail. We know that this position 1, 1 is plane mirror, the position 0, 0 is confocal mirror and the position minus 1, minus 1 is the concentric mirror.

So, these are the g_1, g_2 values. So, we have already seen these in detail, but now I am interested in seeing the longitudinal modes means the resonance frequencies. So, the resonance frequency for the plane mirror is ν_q is equal to q times ν_F , in other words the curvature dependent term is 0.

When we come to the confocal mirror, we get ν_q is equal to q times ν_F plus half ν_F that is midway we recall that this is for the plane mirror. So, ν_q and $\nu_q + 1$. So, for the q th

order of the confocal resonator is here. So, this is let me use a different color. So, this is νq of the confocal mirror confocal mirror which is shifted by half times νF half νF νf .

So, confocal mirror has νq is equal to q plus half νF and we just calculated for the concentric mirror resonator as νq is equal to q times νF plus $1 \nu F$. If we take another symmetric mirror resonator, remember all symmetric mirror resonators g_1 is equal to g_2 which has to lie on this line.

So, for the symmetric mirror resonator that I had chosen it was 0.2 times please see this is the additional term is 0, additional term is half times νF and here the additional term is 1 times νF that is shifted by $1 \nu F$. The one which I calculated for 0.2 is somewhere here.

So, it is about 0.2 times νF if you take another symmetric mirror resonator it will be here, it will be here and so on. Because the line y is equal to x or g_2 is equal to g_1 represents all symmetric mirror resonators and the line from here concentric to plane mirror resonator represents stable resonators.

And, therefore, we see that the curvature dependent term will vary from 0 to $1 \nu F$. For all symmetric resonators stable resonators the curvature dependent term that is the additional term the second term varies from 0 to νF . For any other resonator which is non symmetric resonator we need to calculate using equations 1, 2 and 3.

So, I would recommend that you work out some examples, some examples will be there in the weekly assignment as well and find out what is the frequency shift that we get for different resonators with respect to or with reference to the resonance frequencies of the plane mirror resonate.

So, that brings us to the end of this part of the resonator and in the next part, we will see the laser where the gain medium, the amplifying medium is placed inside a resonator and we have amplification and feedback by the resonator which leads to was a LASER.

So, we will see the dynamics of the LASER and how the LASER reaches steady state oscillation, the importance of pump, the importance of the resonator in determining the output characteristics of the LASER. So, we will stop at this point.

Thank you.
