elastic scattering e-N

$$\frac{d\sigma}{d\Omega} = \left(\frac{d\sigma}{d\Omega} \right)_{\text{Mott}} \cdot \left(\frac{1}{1 + \frac{2E}{M} \sin^2 \theta/2} \right) \cdot \left[\frac{G_E^2 + \tau G_M^2}{1 + \tau} + 2\tau G_M^2 \tan^2 \theta/2 \right]$$

$\tau = \frac{Q^2}{4Mc^2}, \quad Q^2 = -q^2$
 $q = (p - p')$
 p : initial mom. of elec.
 p' : final "

(Rosenbluth formula)

In case of extended objects, and we considered in fact the elastic scattering of the electrons on hadrons like proton, and then we said in the case of elastic scattering e-N scattering electron nucleon scattering in particular we can consider electron proton scattering. The differential cross section can be written as the differential cross section corresponding to the point particle scattering without the nuclear spin effect times and the recoil effect of the electron has of the proton has to be added to this $2E/M \sin^2 \theta/2$ in the denominator times the charge and charge distribution and the electromagnetic interaction part, so electrodes the magnetic interaction part which is for a point particle would correspond to the magnetic dipole interaction.

Here, in the case of particles which are not point particles, we will have to consider form factors. So, there are two form factors, one is the electric form factor, and magnetic form factor. And they appear in the expression for the differential cross section in this fashion plus $2\tau G_M^2 \tan^2 \theta/2$, where τ is equal to Q^2 over $4M$

square C square where Q square is equal to minus Q square and Q itself is basically the realized the for momentum transfer. So, p corresponds to the initial momentum energy and momentum of electron p , and p prime is the final momentum of the electron, this we discussed yesterday.

(Refer Slide Time: 03:14)

And we also discussed that in the case of high energy electron beams, there are we have seen $e p$ not just elastically scattering to $e p$, but can go to some $e x$ other particles, x could in general be any number of hadrons. So, in one particular case, we saw p the proton itself and π over in that were in general it could be any different hadrons a, b, c etcetera are hadrons either mesons or baryons. So, this is inelastic scattering such an elastic scattering let us represent in fashion as e minus in the initial state and e minus in the final state and proton in the initial state, but going into different hadrons in the final stage right.

So, I can picturize it in this fashion. We already said that the effect of electron interaction with proton can be picturized in terms of exchange of photons and that is what we have here. Now, let us look at this inelastic case and then see what are the changes that we had to make the earlier formula that we had here is basically the called the Rosenbluth formula and G_E and G_M are the electric and magnetic form factors which depend on Q square.

(Refer Slide Time: 05:32)

Inelastic case:

$$\left(\frac{d^2\sigma}{d\Omega dE'} \right) = \left(\frac{d\sigma}{d\Omega} \right)_{\text{Mott}} \left[W_2(q^2, \nu) + 2W_1(q^2, \nu) \tan^2 \frac{\theta}{2} \right]$$

$$\nu = E - E'$$

$$q^2 = (p - p')^2$$

So, we take in the case of inelastic case, we consider an expression similar to that of the Rosenbluth formula and write it as $d^2\sigma/d\Omega dE'$. One difference here is compared to the earlier elastic case is that we are also differentiating it with respect to E' or taking the derivative varying the final electron energy. So, remember our earlier discussion, we had said that in the elastic case the final energy of the electron is fixed, you get a particular value for the electron. And if you look at the experimental spectrum, you indeed get a large number of points at E' is equal to whatever the kinematically allowed value you have a fixed value. But in the case of inelastic collisions, this electron transfers some of the energy to the other particles, and then the energy of the electron because the weight goes x .

If you look at the earlier expression earlier picture, $e p$ going to $e x$, x need not to be a particular particle right it can be any many different hadrons. In that case, the energy of the electron will not be fixed; it will vary depending on what are the other particles, what their masses are and what their energies are etcetera. So, we will get an energy distribution for the electron in the final stage. So, therefore, we can consider their electron energy spectrum and see that it will now depend on the form factors similar to the earlier case, but the expression is similar to the earlier case, by earlier case of elastic scattering, but the structure the form factors are now slightly different. So, they are called actually the structure functions.

And they will be usually written as W_2 q^2 ν W_1 q^2 ν functions of q^2 ν q^2 and ν . I will tell you what ν is in a moment times $\tan^2 \theta$ by 2 the θ dependence is similar. The same there is a term, which does not depend on θ^2 and there is a term which depends on $\tan^2 \theta$ by 2. In addition to that, of course, $d\sigma/d\Omega$ Mott has some θ dependence, but apart from the Mott scattering differential cross section which corresponds to the point like particle without the spin considered in a same side this one, spin of the target which is considered or without the magnetic interaction.

So, this structure of function this W_1 and W_2 are called the structural functions and there is no recoil factor that we will consider in these cases, because there is no final proton that we are it is not the elastic scattering that we have considering, it is an inelastic scattering that we are considering. And ν itself is basically $E - E'$ and q^2 of course, is similar to the earlier case $p - p'$ square. So, in addition to the q^2 , the $E - E'$ is another variable which can independently vary compared to q^2 . Let us see how that goes. So, the difference therefore, is that compared to the earlier case is that the structure functions are now functions of not only q^2 , but also ν which is basically the difference in the energy of the final and initial electrons.

(Refer Slide Time: 09:57)

Elastic sat:

$$e p \rightarrow e p$$

mom: $p_e, p_p : p_e', p_p'$

$$p_e + p_p = p_e' + p_p'$$

$$p_p' = (p_e - p_e') + p_p$$

$$(p_p')^2 = q^2 + p_p^2 + 2q \cdot p_p$$

$$\frac{E_p'^2 - \vec{p}_p'^2}{c^2} = q^2 + M^2 c^2 + 2 \frac{(E - E')}{c} M c$$

$$\underbrace{\frac{E_p'^2 - \vec{p}_p'^2}{c^2}}_{m^2 c^2} = q^2 + M^2 c^2 + 2 \nu M \Rightarrow \boxed{2 M \nu = -q^2}$$

$p_e = (\frac{E}{c}, \vec{p}_e)$
 $p_e' = (\frac{E'}{c}, \vec{p}_e')$
 $p_p = (M c, 0)$
 $p_p' = (\frac{E_p'}{c}, \vec{p}_p')$

So, let us look at why that ν is now not an independent variable unlike in the case of elastic case. So, let us consider in the elastic case first elastic scattering say $e p$ go into $e p$ let me denote the momenta as p_e for the initial electron p_p for the final electron; and p'_e for the final electron, and p'_p for the final proton. In these are four momenta, which means that the first or the zeroth component is energy of the electron. In fact, E/c , and the three momentum; and p'_e similarly is E'/c , P'_e . And p_p is at rest initially, so it only has the mass of the proton and no three momentum p'_p is let us say some E'_p and P'_p all right.

So, energy momentum conservation will tell you that the four momenta addition of the four momentum in the initial case is equal to P'_e plus P'_p the sum of the final momentum squared. This includes both energy conservation and momentum conservation. Zeroth component will give you the energy conservation, and the one, two, three components will give you the momentum conservation.

Now, let me write it in a different way P'_p is equal to P_e minus P'_e plus P_p . So, if I square this P'_p square is equal to what is there in this bracket is basically q , so it is q^2 plus P_p^2 plus $q \cdot P_p$. This is essentially equal to well left hand side is mass of the proton square the four momentum square is equal to the mass square which we saw yesterday let me actually write it again.

So, this is equal to E_p^2/c^2 in fact, E_p^2/c^2 minus P'_p square is equal to q^2 plus similarly this only has the P_p only has the zeroth component which is $M^2 C^2$ plus $q \cdot P_p$. So, there is only where the zeroth component. So, here $Q \cdot b$ is basically E minus E' into so this is twice this thing so two times this into mass into C . And this is $M^2 c^2$ energy momentum relation, M is the proton mass is equal to q^2 plus $M^2 C^2$ plus $2 \nu E$ minus E' I denote by ν and $M C$.

This tells you that $q^2 E/c^2$ there is. So, M^2 cancels with the M^2 on the left hand side and then this will give you the relation that $2 M \nu$ is equal to minus Q^2 square. So, ν is not independent of q^2 , given q^2 ν is given by minus q^2 by $2M$. So, in the elastic case these are not two independent variables.

(Refer Slide Time: 14:56)

Inelastic case:
 $e p \rightarrow e p \pi^0$
 $P_e + P_p = P_e' + P_p' + P_{\pi^0}'$
 $(P_p' + P_{\pi^0}')^2 = W^2 c^2$, invariant mass of $p \pi^0$
 $\Rightarrow W^2 c^2 = [(P_e - P_e') + P_p']^2 = q^2 + M^2 c^2 + 2 M \nu$
 $W^2 c^2 > M^2 c^2 \Rightarrow q^2 + 2 M \nu > 0$

But now for the inelastic case, let us consider the example of $E p$ go into $E p \pi^0$ all right. So, now, you will see that the invariant mass, let me write down the four momentum conservation $P_e + P_p$ is equal to $P_e' + P_p' + P_{\pi^0}'$, where P_{π^0}' is the momentum of the final π^0 and rest of it is similar to the earlier case. So, here again when we consider $P_p' + P_{\pi^0}'$ square this is what we call the invariant mass of the system this is equal to $W^2 c^2$ invariant mass of $p \pi^0$ system.

So, this tells you that $W^2 c^2$ is equal to $(P_e - P_e')^2 + P_p'^2$ which is exactly what we had earlier on the right hand side which is $q^2 + M^2 c^2 + 2 M \nu$. Since, $W^2 c^2$ is always larger than $M^2 c^2$ because it is the sum of $P_p' + P_{\pi^0}'$ square which means $P_e + P_p'$ that is the four momentum of the final proton square itself is $M^2 c^2$ or $M^2 c^2$. And in addition to that you have the part coming from pions moment for momentum. So, $W^2 c^2$ is always larger than $P^2 c^2$ square.

And along with this, so therefore, that will give you that the right hand side $1^2 + 2 M \nu$ cannot now be 0 it can be it has to be always larger than 0 in this case. And there is no such relation and there is no such relation between 1^2 and ν as we had in the case of elastic collisions. In the elastic collision case, it was actually $q^2 = W^2$

replaced by m_p the mass of the proton. So, we had q^2 plus $2 M \nu$ exactly equal to 0; here it is not so. So, these two can 1 square and ν can vary independent of each other alright. So, this is why we have in the expression for differential cross-section in the case of inelastic scattering, the form factors or the structure functions as they are called r functions of two variables 1 square and ν unlike in the case of elastic collisions elastic scattering. Where it is only a function of 1 square and ν is not independent of q^2 there.

(Refer Slide Time: 18:50)

Trade ν to x (dimensionless)

$$x = \frac{Q^2}{2M\nu}$$

elastic scat $\Rightarrow x = 1$

inelastic scat

$$2M\nu - Q^2 > 0$$

$$2M\nu(1-x) > 0 \Rightarrow x < 1$$

$$\Rightarrow 0 < x < 1$$

Side notes:

$$Q^2 = -q^2$$

$$E - E' = \nu = \frac{-q^2}{2M} \text{ (elastic)}$$

Now, usually we can actually write the variable ν in a different fashion or ν and Q^2 square in a different fashion. You can actually trade it to or trade it with a variable x , which is dimensionless, ν is E minus E' , so the dimension of ν is dimensions of energy, but we can define a variable called x as Q^2 square over $2 m \nu$. From now on, we will consider capital Q^2 square instead of small Q^2 square, because we saw that ν is equal to minus Q^2 square over $2 M$ in the elastic case.

And ν is E minus E' usually the electron gives energy to the proton, and therefore the energy of the final electron is always smaller than the energy of the initial electron. So, E minus E' is positive ν is positive and Q^2 square is always negative. So, minus Q^2 square is taken as a positive quantity Q^2 capital Q^2 square.

And elastic scattering gives x therefore, equal to 1; For inelastic scattering, we have $2 M \nu$ minus Q^2 square a larger than 0, so that is equal to or that is equivalent to $2 M \nu > Q^2$

minus x larger than 0. That tells you that x has to be less than 1, because M is always positive ν is always positive therefore, x is always less than 1. And minimum value of x is 0, where Q square is 0, so that gives the range of x as 0 between 0 and 1. So, this is these are the two variables that we should consider Q square and ν , or x and Q square.

(Refer Slide Time: 21:37)

point particle

$$\frac{d\sigma}{d\Omega} = \left(\frac{d\sigma}{d\Omega} \right)_{\text{Mott}} \cdot \left(1 + \frac{Q^2}{2M^2c^2} \tan^2 \frac{\theta}{2} \right)$$

elastic scat (Rosenbluth formula)

$$\frac{d\sigma}{d\Omega} = \left(\frac{d\sigma}{d\Omega} \right)_{\text{Mott}} \cdot \left[\frac{G_E^2 + \tau G_M^2}{1 + \tau} + 2\tau G_M^2 \tan^2 \frac{\theta}{2} \right]$$

$$\tau = \frac{Q^2}{4M^2c^2}$$

Inelastic scat:

$$\frac{d^2\sigma}{d\Omega dE'} = \left(\frac{d\sigma}{d\Omega} \right)_{\text{Mott}} \cdot \left[W_2(Q^2, \nu) + 2W_1(Q^2, \nu) \tan^2 \frac{\theta}{2} \right]$$

Now, consider the let us have a summary the three different cases. We had for point particle case, $d\sigma/d\Omega$ equal to $d\sigma/d\Omega$ mott times 1 plus now Q square divided by $2 M$ square c square $\tan$ square θ by 2. And elastic scattering case the Rosenbluth formula $d\sigma/d\Omega$ equal to $d\sigma/d\Omega$ mott times $G E$ square plus $\tau G M$ square over $1 + \tau$ plus $2 \tau G M$ square $\tan$ square θ by 2. Where τ is Q square over $4 M$ square C square. And in elastic case, we have now e prime not fixed, so therefore, we consider $d^2\sigma/d\Omega dE'$ where E' is the energy of the final electron equal to $d\sigma/d\Omega$ mott times $W_2 Q$ square ν plus twice $W_1 Q$ square ν $\tan$ square θ by 2.

If you look at the these expressions, you see that $G E$ and $G M$ are dimensionless and because the $d\sigma/d\Omega$ and $d\sigma/d\Omega$ mott both have the same dimensions. Whereas, W_2 and W_1 have dimensions of 1 over energy, because on the left hand side we have $d^2\sigma/d\Omega dE'$. So, there is a 1 over these structure functions are dimensionless have dimensions of inverse, inverse dimensions of energy.

Now, let us take actually the inelastic scattering case as kind of a general expression supposing this is the general case. So, the expression is written in terms of W_1 and W_2 in the general case then W use in the elastic and inelastic cases can be considered in this fashion.

(Refer Slide Time: 25:04)

elastic scatt.
 Let, $G_E = G_M = G$
 $W_1^{el} = \frac{Q^2}{4M^2 c^2} \cdot G^2 \delta\left(\nu - \frac{Q^2}{2M}\right)$
 $W_2^{el} = G^2 \delta\left(\nu - \frac{Q^2}{2M}\right) \Leftarrow \frac{G_E^2 + \tau G_M^2}{1 + \tau} = G^2$

Let us consider the elastic scattering case not point particle, but particles like protons with extended charge distribution and composite particle, compositeness itself is not coming in here the extended particle not point like particle. We will consider an assumption that assume that G_E is equal to G_M just to illustrate this and make it a simple case. So, G_E is equal to G_M and denoted by some common G . In that case, if you compare these expressions Rosenbluth, and in elastic case expressions, then you can see that W_1 let me denote it by W_1^{el} corresponds to Q^2 square over $4 M^2$ square C^2 square into G^2 square into $\delta(\nu - Q^2 / 2 M)$.

You remember the elastic case ν is always equal to Q^2 square over $2 M$, so that is what we have done we have taken this expression and that $1 / (1 + \tau)$ in the Rosenbluths expression say here is cancelled by the $1 + \tau$ times G_E^2 square coming from the numerator when G_E is equal to G_M . And then $2 M^{el}$ is equal to G^2 square $\delta(\nu - Q^2 / 2 M)$, this is because G_E^2 square plus τG_M^2 square over $1 + \tau$ is essentially equal to G^2 square, now this is one thing. And G^2 square is a function of Q^2 square. So, we have this expression here keep that in mind.

(Refer Slide Time: 27:24)

point particle scat.

$$W_1^{\text{point}} = \frac{Q^2}{4M^2 c^2} \delta(\nu - \frac{Q^2}{2M}) \quad \left| \begin{array}{l} \delta(ax) \\ = \frac{1}{|a|} \delta(x) \end{array} \right.$$

$$W_2^{\text{point}} = \delta(\nu - \frac{Q^2}{2M})$$

dimensionless x :

$$2M c^2 W_1^{\text{point}} = \frac{Q^2}{2M \nu} \delta(1 - \frac{Q^2}{2M \nu})$$

$$\Rightarrow 2M c^2 W_1^{\text{point}} = x \delta(1-x)$$

$$\nu W_2^{\text{point}} = \delta(1-x)$$

And let us go to the case of point particle scattering then the W_1 point particle is equal to Q^2 over $2M$ sorry Q^2 over $4M^2 c^2$ delta ν minus Q^2 over $2M$, and W_2 is which is delta ν minus Q^2 over $2M$. In terms of the dimensionless quantity x , $2M c^2 W_1^{\text{point}}$ is equal to Q^2 over $2M \nu$ delta 1 minus Q^2 over $2M \nu$. Using the property of the delta function that delta ax is equal to $1/|a|$ delta x , this is the property of the delta function which can be easily verified. This gives you $2M c^2 W_1^{\text{point}}$ is equal to this is nothing but x delta 1 minus x . And similarly you have W_2^{point} is equal to $1/\nu$ delta 1 minus x or I can write this as νW_2^{point} is equal to delta 1 minus x .

Why are we doing this exercise? What we are saying is that if you look at this inelastic scattering expression $d^2\sigma/d\Omega dE'$ in terms of W_1 and W_2 the structure functions and the Mott scattering, then we see that if the particle that it scatters on is point particle, we will essentially see that there is no Q^2 dependence there in the structure function. It depends only on the dimensionless quantity x . So, there is no particular energy scale associated with this thing. The form factor is not there. It is independent of the energy.

Remember our earlier discussions on the form factor, we started with saying that if the particle were not actually if the charge distribution was not really point like charge distribution then we will have to consider the charge density not as a delta function, but

as some distribution specially varying distribution or specially distributed charge case. In that case, there is a form factor that will come in their expression for cross-section, differential cross-section, which the form factor itself will now depend on the energy exchange between the electron and the proton.

And now what we are saying is that if it was a point if it is a point particle, it did not have any energy dependence, which is something which we had discussed earlier. But at this point what is going on is that if you consider very large energy, very large meaning a mean of the order of 10 G V etcetera for the electron, then the electron may be able to penetrate inside the protons. And then if it sees point like structures there what we can expect as the scattering with structure functions which denote and depend on Q^2 that is what we have said right.

(Refer Slide Time: 32:31)

So, what we expect in the case of in such cases. For example, if you plot νW_2 as a function of Q^2 for scattering from point like particles or point particles, what we expect is an independent or as what we expect νw to be an independent function of Q^2 meaning it is a constant compare our as far as Q^2 is concerned. It is independent of Q^2 . So, if you consider if you do an experiment and then plot the νw , how do you do that, it is exactly like earlier case from the theoretical expression model that you have which is given in the earlier slides. You try to fit to the observed

data for various different Q^2 values and then see that the extracted W^2 behaves like this that is it is independent of Q^2 .

(Refer Slide Time: 34:22)

This is the expectation and indeed experimentally verified this one which says that when we actually look at large and high energy scattering of the electron on the proton so this is essentially the proton that we are considering then electrons start seeing it high energies it penetrates the proton say. It starts seeing the inside structure of the proton. And it looks like there are point like structures on which the electron scatters. Say for example, if you take the picture of proton made of three quarks, then you will see that you can imagine that the electron interacts only with a particular quark inside the proton; the other quarks are just spectators in this interaction or spectators of this interaction.

In that case, you will see the behavior of this point like particle scattering reflected in the structure functions behavior of the structure function which means that νW^2 for example, is independent of Q^2 . This is seen by experiments and therefore, we can infer that there are structures points like structures inside proton. So, this indicates point like structure inside the proton. Of course, we will have to investigate a little further and then study a little more to have a better feeling and better understanding of this. And to also confirm that there are this point like particles and they indeed correspond to what we

call the quark in the quarks in the quark model. And consistently we can build the picture which is which agrees with the experimental results.

So, we will take on that in the next discussion, taking this further to understand these sub structures in a little better way.
