So, we will continue our discussion on the interaction of charged particles with electromagnetic field in a quantum picture.

(Refer Slide Time: 00:43)

And in relativistic case, essentially this is what we call a quantum electrodynamics, but we will come to the formal quantum electrodynamics as a field. The quantum field theory at a little stage, but this is basically to build or give way to such a quantum field theory how to think about that.

So, we will consider the discussion that we have been doing in the past couple of lectures forward.

(Refer Slide Time: 01:18)

Gauge freedom

$$A^\mu = (\phi, \vec{A})$$

$$A^\mu \rightarrow A^\mu + \partial^\mu \chi = A'^\mu \quad \rightarrow (1)$$

$$\partial_\mu A'^\mu = 0$$

$$A^\mu \rightarrow A^\mu + \partial^\mu \lambda = A''^\mu \quad \rightarrow (2)$$

$$\partial_\mu A''^\mu = \partial_\mu A'^\mu + \partial_\mu \partial^\mu \lambda$$

$$= 0 + \left(\frac{1}{\epsilon_0}\right) \text{ for particular } \lambda$$

So, we were discussing the gauge freedom associated with the 4 vector potential picture of the electromagnetic field. So, we said we could express the electromagnetic potential  $A_\mu$  express, the electromagnetic field in terms of the scalar potential and the vector 3 vector potential putting them together as components of a 4 vector, we can consider  $A_\mu$  the 4 vector as the 4 vector potential representing the electromagnetic field.

And we said, if we consider the measurable quantities electric and magnetic field  $E$  and  $B$  associated with this  $A_\mu$ , then we will see that the  $A$  is not uniquely defined or fixed we can actually take  $A_\mu$  to  $A_\mu$  plus derivative of some scalar function  $\chi$  which will still give you the same electric and magnetic field and this freedom to choose any  $\mu$  related by this relation is basically called gauge freedom and that is a kind of an arbitrary defining the potential.

But it is taken as an advantage in quantum electrodynamics we will come to that a little later when we discuss the gauge symmetry, but at the moment this lets us fix the  $A_\mu$ . So, that  $\partial_\mu A^\mu$  is equal to 0 that is  $A_\mu$  can be made divergence less  $\partial_\mu A^\mu$  is equal to 0 by appropriately choosing the scalar function  $\chi$ .

Now, this is what we saw yesterday and even after fixing this there still we can actually transform  $A_\mu$  to  $A_\mu$  plus  $\partial_\mu \lambda$  the secondary  $A_\mu$  is the now  $A_\mu$  now  $\mu$  that satisfies the. So, let me call this  $A_\mu$  prime to avoid any confusion. So,  $A_\mu$  prime is the new field and  $A_\mu$  prime can be transferred now to  $A_\mu$  prime plus some

$\nabla \cdot \mathbf{A}' = \nabla \cdot \mathbf{A} + \nabla^2 \chi$  and then of course, this should also give you the same electric and magnetic field because it is similar to the earlier transformation.

But we have to check whether the condition the divergence condition of a prime  $\mathbf{A}$  is also conserved if you take the divergence of the new field a double prime you then we will have divergence of a prime  $\mathbf{A}$  plus  $\nabla^2 \chi$ . So, this first term is equal to 0 and second term can be made 0, if we choose a  $\chi$  appropriately. So, this is equal to 0 for particular  $\chi$ .

So, first one transformation fixes the divergence of  $\mathbf{A}$ . So, that it is divergence less and then we see that still there is a freedom to choose a the potential and we see that there is always possibly this always possible to choose a double prime by adding a derivative term of a scalar function again to the yet prime as in the case of equation 2 this will not change anything, it will not change this electric and magnetic field the physical quantities neither will it change the condition that the a prime is divergence less or it therefore, a double prime is also divergence less.

If  $\chi$  satisfies the condition that  $\nabla^2 \chi = -\nabla \cdot \mathbf{A}$  is equal to 0. So, the second transformation is not for any scalar function unlike the first transformation where  $\chi$  could have been any scalar function  $\chi$  is not any scalar function  $\chi$  is the scalar function which satisfies the condition  $\nabla^2 \chi = -\nabla \cdot \mathbf{A}$  is equal to 0. So, that is basically the thing we will return back to this when we discussed explicit expression for  $\mathbf{A}$  later.

(Refer Slide Time: 07:14)

$$\begin{aligned}\vec{E} &= -\vec{\nabla}\phi - \frac{\partial \vec{A}}{\partial t} \\ \vec{B} &= \vec{\nabla} \times \vec{A} \\ \text{Satisfied by } \begin{cases} A^\mu \\ A'^\mu = A^\mu + \partial^\mu \chi, \text{ any scalar function } \chi \\ A''^\mu = A'^\mu + \partial^\mu \lambda, \partial_\mu \partial^\mu \lambda = 0 \end{cases} \\ \Rightarrow \partial_\mu A'^\mu &= 0 = \partial_\mu A''^\mu.\end{aligned}$$

Now, this actually says E is equal to minus del phi minus dou A over dou t and B equal to curl of A as satisfied by A mu or a prime mu which is essentially equal to mu plus dou mu chi any scalar function chi and A double prime mu which is a prime mu plus dou mu lambda where lambda is a scalar function. So, that dou mu dou lambda is equal to 0 and this gives dou mu A prime mu is equal to 0 and also dou mu a double prime mu equal to 0 divergence.

So, we have the same physical situation for any of these fields and then in air double A, we will see that A double prime mu, we have fixed the arbitrariness. So, that unique in the sense that I mean that fix that is an in the sense that you cannot add any more terms in the other thing because lambda is already lamb the choices of chi and lambda will fix this thing for the condition for A mu prime divergence less mu a prime is satisfied here.

Let us look at the Maxwell's equations with all these conditions applied to the potential.

(Refer Slide Time: 09:14)

Maxwell's eqn.

$$\partial_\nu \partial^\nu A^\mu - \partial^\mu (\partial_\nu A^\nu) = J^\mu$$

Gauge choice  $\Rightarrow \partial_\nu A^\nu = 0$   
(Lorenz gauge condition)

$$\partial_\nu \partial^\nu A^\mu = J^\mu ; \quad \square^2 \equiv \partial_\nu \partial^\nu$$

$$\square^2 A^\mu = J^\mu$$

Maxwell's equation written in terms of the potential was  $\partial_\nu \partial^\nu A^\mu - \partial^\mu (\partial_\nu A^\nu) = j^\mu$ . So, if we have a condition that gauge choice is such that  $\partial_\nu A^\nu = 0$  as we discussed in earlier case this condition is called Lorenz gauge condition.

In that case the second term from the Maxwell's equation drops out and then we have  $\partial_\nu \partial^\nu A^\mu = j^\mu$  or in a slightly more compact way we can write it as  $\square^2 A^\mu = j^\mu$  where  $\square^2$  is equivalent to  $\partial_\nu \partial^\nu$  or  $\partial_\mu \partial^\mu$  where  $\mu$  is summed over and in that case, I can write the  $\square^2 A^\mu = j^\mu$  slightly in need a way of writing it meaning the same thing in any case.

Now, let us come to solutions of this equation this is the Maxwell's equation with Lorenz gauge condition applied maybe I should highlight this. So, this is our Maxwell's equation with Lorenz condition. So, let us look at it. So, we have  $\square^2 A^\mu = j^\mu$ .

(Refer Slide Time: 11:17)

$$\square^2 A^\mu = j^\mu = 0, \quad \text{free em waves (free photon)}$$

Solution:

$$A^\mu = \epsilon^\mu(q) \cdot e^{-iq \cdot x}$$

$$q \cdot x = q_\mu x^\mu$$

$$\partial_\nu A^\mu = \partial_\nu (\epsilon^\mu(q) \cdot e^{-iq \cdot x})$$

$$= \frac{\partial}{\partial x^\nu} \left[ \epsilon^\mu(q) \cdot e^{-i(q_0 t - q_1 x - q_2 y - q_3 z)} \right]$$

$\mu$  equal to  $j_\mu$  equal to 0 for free electromagnetic waves or I would say in the quantum picture free photons, we are not quantized it yet, but let us say that we can do that and then think about electromagnetic field as collection of photons in that case  $A_\mu$  represent the photon. Now we are actually deviating a little away from the earlier interpretation or earlier picture of giving more physical meaning to the electric field and the magnetic field and then considering the 4 potential as an auxiliary and function that was the earlier picture and then we said that we can actually how different the potential is even which will give you the same physical situation.

Now, in the quantum electrodynamics we will deviate from this picture and then say that photon which is the quantum of the electromagnetic field is more meaningful physically and the field associated with that is the potential where is equal to the potential  $A_\mu$  and therefore,  $A_\mu$  is the one which represents the photo associated to that any photon we can actually think about the electric field and the magnetic field.

When you come down to a fine, see the picture of the photon in the non relativistic case we will see the electric field and magnetic field associated with photons with certain relations between them, but  $A_\mu$  therefore, takes a more physical meaning in quantum electrodynamics and arbitrariness can be fixed by choosing the gauge conditions and then it is somewhat uniquely fixes the potential corresponding to the or the yeah the

potential corresponding to the photon or the wave function corresponding to the photon or the field corresponding to the function.

At this moment I will be a little vague in defining what is wave function what is the field what is the potential etcetera basically I will interchange I called  $A_\mu$  sometimes as feel sometimes as the wave function corresponding to the photons sometimes as the potential. So, all these are the same thing, but looking at from different pictures accordingly the interpretation is slightly different, but basically it is the same entity. So, for the time being we will not distinguish it clearly.

As we come to the clear representation of the quantum field corresponding to the photon we will assay as an operator that is the correct picture in quantum field theory or quantum electrodynamics we will talk a little more about what is the quantum field  $A_\mu$ , but essentially that is the same as the potential that we are considering in a relativistic electron dynamics. So, this does the box square is essentially called DLM version. So, DLM version  $A_\mu$  acting on DLM version is an operator which acts on  $A_\mu$  here to give you 0 for 3 photons.

Solution well this is basically an easy guess if I take  $A_\mu$  to be some constant function constant for vector as far as  $x$  is concerned DLM is an operator which acts on the coordinates in order on the momentum. So, I can take this for some constant function in a constant in  $x$  function which is constant in  $x$ , but could depend on momentum  $A$  for vector and explicit coordinate dependence in an oscillatory exponential minus  $i q \cdot x$  where  $q \cdot x$  is for vector dot product  $q_\mu x_\mu$  where  $\mu$  is summed over ok.

Let me convince you that it is actually indeed a solution or what are the conditions that anything should satisfy for this to be a solution. So, let me act on it by  $\square_\mu \square_\mu A_\mu$  is equal to  $\square_\mu$  acting on  $\epsilon_\mu q E^{\text{power}} \text{minus } i q \cdot x$  which is equal to  $\square_\mu$  by  $\square_\mu x_\nu$  acting on the same thing  $\epsilon_\mu q E^{\text{power}} \text{minus } i q \cdot x$  minus  $q_2 y$  minus  $q_3 z$  ok.

(Refer Slide Time: 17:59)

$$\begin{aligned}
 \underline{\underline{y=0}} \quad \frac{\partial A^\mu}{\partial t} &= \frac{\partial}{\partial t} \left[ \epsilon^\mu(q) e^{-i(q_0 t - \vec{q} \cdot \vec{x})} \right] \\
 &= \epsilon^\mu(q) \cdot (-i q_0) e^{-i(q_0 t - \vec{q} \cdot \vec{x})} \\
 &= (-i q_0) A^\mu \\
 \frac{\partial A^\mu}{\partial x} &= \frac{\partial}{\partial x} \left[ \epsilon^\mu(q) e^{-i(q_0 t - q_1 x - q_2 y - q_3 z)} \right] \\
 &= (+i q_1) A^\mu
 \end{aligned}$$

So, now let us take case by case  $\mu$  equal to 0 which is  $\frac{\partial}{\partial t}$  of  $A^\mu$  which is equal to  $\frac{\partial}{\partial t}$  of  $\epsilon^\mu(q) e^{-i(q_0 t - \vec{q} \cdot \vec{x})}$ . So, there is only one particular place where  $t$  appears on the right hand side it is exponential minus  $i q_0 t$ . So, when I take the derivative  $\epsilon^\mu(q)$  is independent of  $t$  comes out  $e^{-i(q_0 t - \vec{q} \cdot \vec{x})}$  is minus when the derivative acts on its minus  $i q_0$ .

$e^{-i(q_0 t - \vec{q} \cdot \vec{x})}$  and other things remain the same minus  $\vec{q} \cdot \vec{x}$ . So, this is essentially equal to minus  $i q_0 A^\mu$  all right. So, now, now similarly  $\frac{\partial}{\partial x} A^\mu$  is equal to  $\frac{\partial}{\partial x} \epsilon^\mu(q) e^{-i(q_0 t - q_1 x - q_2 y - q_3 z)}$ . So, that will give you minus of minus plus  $i q_1 A^\mu$ . So, that is one thing.

(Refer Slide Time: 20:18)

$$\partial_\nu \partial^\nu A^\mu = \frac{\partial^2 A^\mu}{\partial t^2} - \frac{\partial^2 A^\mu}{\partial x^2} - \frac{\partial^2 A^\mu}{\partial y^2} - \frac{\partial^2 A^\mu}{\partial z^2}$$

$$\frac{\partial A^\mu}{\partial t} = (-iq_0) A^\mu$$

$$\frac{\partial^2 A^\mu}{\partial t^2} = (-iq_0) \frac{\partial A^\mu}{\partial t} = (-iq_0)(-iq_0) A^\mu = -q_0^2 A^\mu$$

$$\frac{\partial^2 A^\mu}{\partial x^2} = -q_1^2 A^\mu, \quad \frac{\partial^2 A^\mu}{\partial y^2} = -q_2^2 A^\mu$$

$$\frac{\partial^2 A^\mu}{\partial z^2} = -q_3^2 A^\mu$$

Now, what we want to have  $\partial_\nu \partial^\nu$  acting on  $A^\mu$  which is equal to  $\partial^2$  by  $\partial t$  square acting on  $A^\mu$  minus  $\partial^2$  by  $\partial x$  square acting on  $A^\mu$  minus  $\partial^2$  by  $\partial y$  square acting on  $A^\mu$  minus  $\partial^2$  over  $\partial z$  square acting on  $A^\mu$  say  $\mu$  and we had  $\partial$  by  $\partial t$  or  $A^\mu$  is equal to  $-iq_0 A^\mu$ .

So,  $\partial^2 A^\mu$  by  $\partial t$  square is equal to  $-q_0^2$  independent of  $t$  and  $\partial$  by  $\partial t$  acting on  $A^\mu$  which is another  $-iq_0 A^\mu$  which is equal to  $-q_0^2 A^\mu$  and  $\partial^2$  by  $\partial x$  square  $A^\mu$  will give you  $-q_1^2 A^\mu$  and  $\partial^2$  by  $\partial y$  square  $A^\mu$  is  $-q_2^2 A^\mu$  and  $\partial^2$  over  $\partial z$  square  $A^\mu$  is equal to  $-q_3^2 A^\mu$  putting it together  $\partial_\nu \partial^\nu$ .

(Refer Slide Time: 22:27)

$$\partial_\nu \partial^\nu A^\mu = (-q_0^2 + q_1^2 + q_2^2 + q_3^2) A^\mu$$

$$= -q^2 \cdot A^\mu$$

Maxwell's eqn.  $\square^2 A^\mu = 0$

$$\Rightarrow -q^2 A^\mu = 0$$

$$\Rightarrow q^2 = 0$$

$$q^2 = \left(\frac{E}{c}\right)^2 - \vec{q}^2 = m^2 c^2 \} \Rightarrow \text{massless photon}$$

$\partial_\nu \partial^\nu A^\mu$  is equal to minus  $q_0^2$  plus  $q_1^2$  plus  $q_2^2$  plus  $q_3^2$  which is equal to minus  $q^2$  times  $A^\mu$ .

And we have Maxwell's equation with Lorenz gauge condition  $\square^2 A^\mu = 0$  and that gives us minus  $q^2 A^\mu = 0$ , we essentially need  $q^2$  to be equal to 0 and what is  $q^2$ ?  $q^2$  is equal to  $q_0^2$  which is essentially  $E^2/c^2$  minus  $\vec{q}^2$  which is equal to  $m^2 c^2$  and when we say  $q^2 = 0$ ,  $m^2$  is equal to 0,  $q^2$  for vector square is equal to 0.

Now, as we said earlier when we consider the  $A^\mu$  as representing the photon and we associated  $\vec{p}$  for momentum  $q$  with  $A^\mu$  like in this case  $A^\mu$  is equal to  $\epsilon^\mu \exp(-i q \cdot x)$  is what we considered, right. So,  $q$  is essentially then interpreted as the momentum for momentum of the photon and Maxwell's equation gave us for momentum square is equal to 0 for the photon of course, you can ask the question like this was in the case of  $A^\mu$  satisfying the Lorenz condition what about if I consider  $A^\mu$  which is not divergence less then still can I interpret this as the photon with mass equal to 0.

So, this essentially gives you mass less photon I mean when I say mass less photon in the sense it says that photon has no mass, but then you remember this gauge condition is not an additional condition that we can apply we could have applied the gauge condition and

chosen any condition any kind of gauge any conditions that satisfies the gauge transformation.

So, that electric field and magnetic field remains the same from that point of view the physics should not depend on whether I have taken Lorenz gauge or not Lorenz gauge condition or not which means the  $A_\mu$  that satisfies the Maxwell's equation, the way we had written with the gauge condition or some air prime which is not divergence less and do not satisfy the Lorenz gauge condition.

But is derived were related to this  $A_\mu$  through a gauge condition gauge transformation by adding  $A$  or differ by  $A_{\text{dou mu chi}}$  kind of a term then chi is a scalar fit in that case they are physically the same equivalent to each other and therefore, all of those when we consider as photons if in one case, it is mass less, then in all other cases also it should be mass less.

So, this represents the same this thing and then photon in any case whether there is a Lorenz condition applied or not it is mass less only that when you take it in this pattern it is manifestly clear its manifested, there it is very apparently there clearly there. Now let me look at it a little more and then see; what is the interpretation that we can give to epsilon.

(Refer Slide Time: 27:27)

$$\begin{aligned}
 A^\mu &= \epsilon^\mu(q) \cdot e^{-iq \cdot x} \\
 &= (\epsilon^0, \vec{\epsilon}) e^{-iq \cdot x} \\
 \vec{E} &= -\vec{\nabla} \phi - \frac{\partial \vec{A}}{\partial t} = -\frac{\partial \vec{A}}{\partial t} \\
 &= \vec{\epsilon} \cdot (-iq_0) e^{-iq \cdot x} \\
 &= (-iq_0) \vec{\epsilon}(q) e^{-iq_0 t} \cdot e^{i\vec{q} \cdot \vec{x}} \\
 \text{polarization direction : } &\vec{\epsilon}
 \end{aligned}$$

So, we had we had the solution if  $A_\mu$  equal to  $\epsilon_\mu e^{i q \cdot x}$  for the photon field satisfying the Maxwell's equation.

Let me write this  $\epsilon_\mu$  as  $\epsilon_0$  and  $\vec{\epsilon}$   $\epsilon_\mu e^{i q \cdot x}$ . So, I have not explicitly written the  $q$  dependence on the  $\epsilon_\mu$  now it is understood that it depends on  $q$ , it is just for the sake of clarity that we are not adding the bracket with  $q$ . The array what is  $E$  electric field is equal to  $-\nabla \phi - \frac{1}{c} \frac{dA}{dt}$ .

supposing we do not have any electrostatic potential  $\phi$  and electric field is only due to the changing magnetic field like in the case of electromagnetic waves. So, for a free photon we can imagine that there is nothing else, but the changing electric field and changing magnetic field one inducing the other. So, in that case this is equal to 0. So, you have  $-\frac{1}{c} \frac{dA}{dt}$  as the electric field and that is essentially  $\epsilon_0 e^{i q \cdot x}$  acting on this thing will give you  $-i q_0 \epsilon_0 e^{i q \cdot x}$  or  $-i q_0 \epsilon_0$  which depends on  $q_0 e^{i q \cdot x}$ . So, this is basically the electric fields with explicit dependence on the time and  $x$  narrator.

We are familiar with this and the amplitude is given by a complex amplitude here  $-i q_0 \epsilon_0$   $\vec{\epsilon}$  direction of the electric field is the same as the direction of the  $\epsilon_\mu$  with  $\vec{\epsilon}$  and therefore, we can say that polarization direction is of the photon is that of the  $\epsilon_\mu$ .

(Refer Slide Time: 30:53)

Handwritten mathematical derivation of the Lorentz condition for the photon field:

$$\text{Lorentz condition } \partial_\mu A^\mu = 0$$

$$A^\mu = \epsilon^\mu e^{-i q \cdot x} \Rightarrow -i q_\mu \epsilon^\mu = 0$$

$$\epsilon^\mu = (\epsilon^0, \epsilon^1, \epsilon^2, \epsilon^3)$$

$$q_0 \epsilon^0 - q_1 \epsilon^1 - q_2 \epsilon^2 - q_3 \epsilon^3 = 0$$

$$\Rightarrow 3 \text{ indep. components.}$$

Now, let us see what happens to the polarization vector in the case of Lorenz condition, let us look at Lorenz condition which is  $\partial_\mu A^\mu = 0$ .  $A^\mu = \epsilon^\mu E$  power minus  $i q x$  will immediately give you  $q^\mu$  or minus  $i q^\mu \epsilon^\mu$  is equal to 0 when taking when the  $\partial_\mu$  is acted on  $A^\mu$ . So, this says that Lorenz condition says not all the components  $\epsilon^0, \epsilon^1, \epsilon^2, \epsilon^3$  are independent of each other.

But depends through the relation  $q^\mu \epsilon^\mu = 0$  or  $q^0 \epsilon^0 - q^1 \epsilon^1 - q^2 \epsilon^2 - q^3 \epsilon^3 = 0$ . So, for a fixed  $q^\mu \epsilon^\mu$  all the 4 components of  $\epsilon^\mu$  are not independent of each other. So, there is a relation that they had to satisfy therefore, there are only 3 independent that gives 3 independent components.

(Refer Slide Time: 32:49)

Handwritten mathematical derivation on a whiteboard:

$$\begin{aligned} \text{Funktion} \quad \Lambda &= i a e^{-i q \cdot x} \\ \partial_\mu \Lambda &= (i a) (-i q^\mu) e^{-i q \cdot x} \\ \partial_\mu \partial^\mu \Lambda &= (i a) (-q^2) e^{-i q \cdot x} = 0 \\ \therefore q^2 &= 0 \end{aligned}$$

Further we can choose  $\Lambda$  let us choose  $\Lambda$  equal to  $i a e^{-i q \cdot x}$  what is  $\partial_\mu \Lambda$   $\partial_\mu \Lambda$  is equal to  $i a$  minus  $i q^\mu E$  power minus  $i q \cdot x$  and  $\partial_\mu \partial^\mu \Lambda$  is equal to  $i a$  minus  $q^2 E$  power minus  $i q \cdot x$ , but  $q^2$  is equal to 0 says that this is equal to 0.

So, as a scalar function satisfying  $\partial_\mu \partial^\mu \Lambda = 0$  is  $i a e^{-i q \cdot x}$  well this  $i a$  is a fixed is kept like that because of reason that will be clear just now. So, this is 0 because  $q^2$  is equal to 0. So, now, what does that tell you in terms of the change?

(Refer Slide Time: 34:08)

$$\begin{aligned}
 A^\mu &\rightarrow A^\mu + \partial^\mu \Lambda = A^\mu + (ia)(-iq^\mu) e^{-iq \cdot x} \\
 &= \epsilon^\mu e^{-iq \cdot x} + a q^\mu e^{-iq \cdot x} \\
 &= (\epsilon^\mu + a q^\mu) e^{-iq \cdot x} \\
 &= \epsilon'^\mu e^{-iq \cdot x} \\
 (A^\mu \rightarrow A'^\mu = A^\mu + \partial^\mu \Lambda) &\Rightarrow \epsilon^\mu \rightarrow \epsilon'^\mu = \epsilon^\mu + a q^\mu
 \end{aligned}$$

In epsilon corresponding to a change a transformation of  $A_\mu$  to  $\mu$  plus  $\partial_\mu \Lambda$  this is equal to  $A_\mu$  plus  $a q_\mu$ . So, we had  $i a$  minus  $i q_\mu$  exponential minus  $i q \cdot x$ .

So, if I write  $A_\mu$  as  $\epsilon_\mu E^{i q \cdot x}$  then minus plus  $i a$  times minus  $i q_\mu$  is plus  $a q_\mu$  exponential minus  $i q \cdot x$  which is  $\epsilon_\mu$  plus  $a q_\mu$   $E^{i q \cdot x}$  if I denote this by some  $\epsilon'_\mu E^{i q \cdot x}$  as  $A_\mu$  goes to  $A'_\mu$  equal to  $A_\mu + \partial_\mu \Lambda$  with this particular  $\Lambda$  this gives  $\epsilon_\mu$  going to  $\epsilon'_\mu$  which is equal to  $\epsilon_\mu + a q_\mu$  right, fine.

(Refer Slide Time: 35:46)

$$\begin{aligned}\epsilon'^\mu &= \epsilon^\mu + a q^\mu \\ \text{Choose "a" so that } (\epsilon')^0 &= 0 \\ q_0 \epsilon^0 - q_1 \epsilon^1 - q_2 \epsilon^2 - q_3 \epsilon^3 &= 0 \\ \Rightarrow q_0 (\epsilon')^0 - \vec{q} \cdot \vec{\epsilon}' &= 0 \\ (\epsilon')^0 &\Rightarrow \vec{q} \cdot \vec{\epsilon}' = 0 \\ &\Rightarrow 2 \text{ ind components}\end{aligned}$$

So, I have epsilon prime mu equal to epsilon mu plus a q mu now I can choose a. So, that epsilon prime mu the 0 is equal to 0 all right. So, this is why we had taken the lambda in that particular way. So, I can choose this. So, initially we had a condition on epsilon that  $q_0 \epsilon^0 - q_1 \epsilon^1 - q_2 \epsilon^2 - q_3 \epsilon^3 = 0$  now that epsilon prime. So, this is applicable to epsilon primers.

Because its the same this thing satisfying same condition Lorenz condition this is basically the Lorenz condition and changing it by lambda which has  $\partial_\mu \partial_\mu = 0$  will not change the Lorenz condition. So, this actually tells you that  $q_0 \epsilon'^0 - \vec{q} \cdot \vec{\epsilon}' = 0$ .

Let me write it as  $\vec{q} \cdot \vec{\epsilon}' = 0$  since epsilon prime 0 is set to 0 by appropriately choosing appropriately choosing a we have  $\vec{q} \cdot \vec{\epsilon}' = 0$  epsilon 3 prime has 3 components, but then there is a condition  $\vec{q} \cdot \vec{\epsilon}' = 0$ . So, essentially there is a relation between these 3 components and therefore, that gives you 2 independent components.

(Refer Slide Time: 38:05)

Or we can say that photon has 2 degrees of freedom. So, let us summarize what we have been doing we had the Maxwell's equation

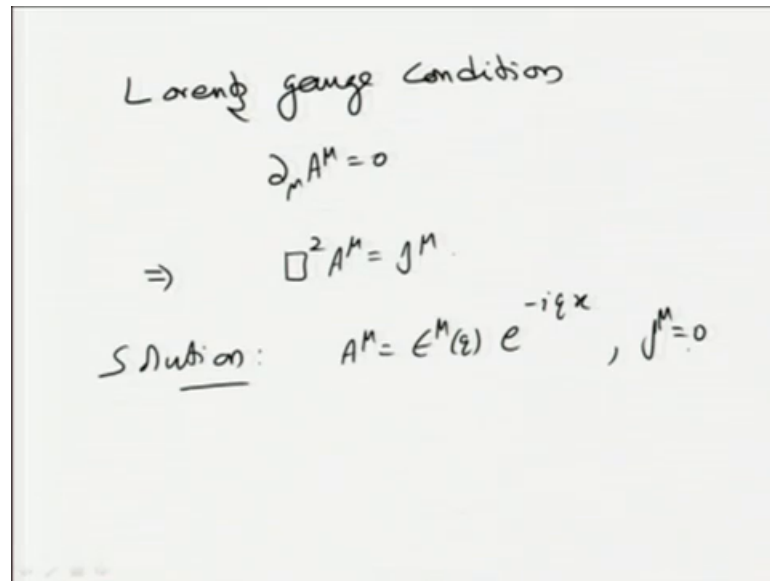

(Refer Slide Time: 38:23)

Maxwell's eqn.  
 $\partial_\mu F^{\mu\nu} = j^\nu$   
 $F^{\mu\nu} = \partial^\mu A^\nu - \partial^\nu A^\mu$   
 $\Rightarrow (\partial_\mu \partial^\mu) A^\nu - \partial^\nu (\partial_\mu A^\mu) = j^\nu$

In terms of field tensor  $f_{\mu\nu}$  is equal to  $j_\nu$  and  $f^{\mu\nu}$  is equal to  $j^\nu$  and we could write  $f_{\mu\nu}$  in terms of vector potential as  $\partial_\mu A_\nu - \partial_\nu A_\mu$  that gave the Maxwell's equation as  $\partial_\mu \partial^\mu A^\nu - \partial^\nu (\partial_\mu A^\mu) = j^\nu$ .

(Refer Slide Time: 39:06)

Handwritten notes on a whiteboard:

Lorenz gauge condition

$$\partial_\mu A^\mu = 0$$
$$\Rightarrow \square^2 A^\mu = j^\mu$$

Solution:  $A^\mu = \epsilon^\mu(q) e^{-iqx}, j^\mu = 0$

Then we had the Lorenz gauge condition  $\partial_\mu A^\mu = 0$ ; this Lorenz gauge condition will not affect physics because we can find out any  $\mu$  which satisfies the gauge condition with the same electric and magnetic field associated with it as the original case and that gives us Maxwell's equation  $\square^2 A^\mu = j^\mu$ , then we considered the solutions  $A^\mu = \epsilon^\mu(q) e^{-iqx}$  for  $j^\mu = 0$  case which is then interpreted as the representing the a free photon without any charge density or current density in the region isolated electromagnetic wave freely propagating in the quantum vector equivalent to a photon represented by  $A^\mu$ .

(Refer Slide Time: 40:30)

$$\Rightarrow q^2 = 0 \quad (\text{massless photon})$$
$$\epsilon^\mu : \text{polarization vector}$$
$$: 2 \text{ degrees of freedom}$$

And that told us that we have  $q^2$  equal to 0 mass less photon and  $\epsilon^\mu$  is essentially the polarization vector in the 4 dimensional case and especially in the 3 dimensional case it is the familiar polarization associated with electromagnetic field and we saw that it has 2 degrees of freedom or a 2 independent components maybe I should write it in that fashion.

(Refer Slide Time: 41:29)

$$\Rightarrow q^2 = 0 \quad (\text{massless photon})$$
$$\epsilon^\mu : \text{polarization vector}$$
$$: 2 \text{ independent components}$$
$$\Rightarrow \text{photon has 2 degrees of freedom}$$

So, this with the Lorenz condition this has 2 independent components that in turn tells us that photon has 2 degrees of freedom we will come to the discussion of the interaction of charged particle with such photons for dolphins in the coming discussion.
